Sign in to LCS, and scroll to the right side of the page. Expand the tiles waffle, and then select the Translation service tile to open the dashboard view for DTS.

**Accessing DTS from within an LCS project**

Create a new project, or open an existing project. On the project dashboard, in the More tools section, select the Translation service tile. Alternatively, on the project dashboard, select the Menu button, and then select Translation service.

**Accessing DTS from the LCS home page vs. accessing it from within an LCS project**

When you access DTS from the LCS home page and create a translation request, you can select the product that is used for the request. To add more requests that use different products, you can just change the product selection. You don't have to close the service and open a different translation project. This option is convenient when you work on multiple product translation projects.

The following illustration shows an example of the DTS dashboard that you open from the LCS home page. This dashboard shows all requests that users from your organization have made from the home page (outside an LCS project).
Because an LCS project is always tied to a product, any translation request that you submit from a project automatically carries the product type and version information from the project. You can’t select a different product for the request.

The following illustration shows an example of the DTS dashboard that you open from within an LCS project. Only the project owner and users who have access to the project will be able to see these requests. Therefore, this option is useful when you work with a group of people on one product translation project in LCS.

In both situations, users who can view the request will have read access. However, to regenerate the request, they must take ownership of it in the dashboard.

Glossary

</tbody>
</table>

For more information about how to use DTS, see [Translate user interface files](#) and [Translate documentation files](#).
This topic provides information about how to translate a user interface (UI) file for Microsoft Dynamics products or solutions.

For more information about the Microsoft Dynamics 365 Translation Service, see Dynamics 365 Translation Service overview. For information about how to translate a documentation file, see Translate documentation files.

Create a translation request

1. In Microsoft Dynamics Lifecycle Services (LCS), on the DTS dashboard, select Add to create a new translation request.

2. Enter the required information for the request.

<table>
<thead>
<tr>
<th>FIELD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request name</td>
<td>Enter a name for the request.</td>
</tr>
<tr>
<td>File type</td>
<td>Select User Interface.</td>
</tr>
<tr>
<td>Product name</td>
<td>Select a product name. If you accessed DTS from within an LCS project, this field is automatically filled in and is read-only.</td>
</tr>
<tr>
<td>Product version</td>
<td>Select a product version. If you accessed DTS from within a LCS project, this field shows the default product version information from the project. However, you can select a different version.</td>
</tr>
</tbody>
</table>
**Translation source language, Translation target language**

Select the set of source and target languages to translate from and to. If your business requires that multiple target languages be translated for the same source language, you can select all the target languages in one request. Select each target language by using the checkbox next to the language's name. This approach helps you save time and also lets you track the status of all the target language translations in one request. The fields list all the languages that are supported for the selected product name and version. Language names that are shown in **bold** are General Availability (GA) languages for Microsoft Dynamics products. Therefore, product-specific machine translation (MT) models are available in those languages, and the MT model is trained on the terminology for Microsoft Dynamics. For non-GA languages, the MT model uses the general domain training.

Upload files

Select the plus sign (+) in each section to open the **File upload** page.

**Upload the files to translate (Required)**

Create one zip file that contains all the UI files in the source language that you want to translate from. The zip file can include different file types, provided that the file types are supported for the product. For more information about supported file types, see [Supported products](#). Note that DTS doesn't change the source files that you upload. The source files are only used to create files in the corresponding target languages you requested.

**Upload XLIFF translation memory files (Optional)**

If you have XLIFF TM files from a previous UI translation request, or if you used the Align tool to create an XLIFF TM, create a zip file that contains all TM files before you upload them. Strings that match are then recycled to help guarantee consistency between product versions. For more information about XLIFF TMs, see [Translation memory files](#).

If you created the translation request for multiple target languages, you must select which target language the TM file is for.

You have an option to create a custom **MT model** that is trained with the translation memory file that you're
After translation is completed, if you use this option, the request might take longer to be completed. You must select either Yes or No before you can continue with the TM file upload.

After you've finished uploading files, select Submit to start the translation process.

After you submit the request, a new request ID is created on the DTS dashboard. If you submitted the request for multiple target languages, the status of each target language is shown on a separate line that has the same request ID. If you select a line on the dashboard, the dashboard page will be extended to the right to show a summary of the request information.

To see the request status, click a request ID link on the dashboard. The Request status tab shows the source files list you uploaded with the summary of the request information.

Note that the processing time depends on the number of requests that are in the DTS queue and the word count in the source files that you submit.

- UI translation requests that don't have an XLIFF TM can be completed in a few minutes, depending on the file size.
- If a UI translation request does have an XLIFF TM, the time that is required depends on the type of MT model:
  - Creation of a custom MT model requires two to three business days.
  - If you're using a generic MT model, requests can be completed in a few minutes, depending on the file size.

After translation is completed

When your translation request has been processed, you will receive an email notification from DTS. You can then view the result on the Request output tab of the Request details page.
For UI translation requests, two types of output file are available after the translation process is completed.

- **For translation review** – Download the XLIFF file to review and, as required, edit the translations. The file shows the source and target languages side by side.
- **Translated native format** – Download this file if you don't intend to review or edit the translations. *Native format* means that the file is in the same format as the source file that you submitted.

Click an individual file link or the download links to download a single file, all files for one target language, or all files for all target languages in one zip for convenience.

**Review and edit the translations in the XLIFF file**

We recommend that you review and edit the translations in the XLIFF file that DTS provides, to verify that the translation output meets your product's quality standards. For more information about how to edit the XLIFF file, see Translation memory files.

**Regenerate output files**

When you've finished reviewing and editing the translation files in XLIFF, you must regenerate the translated native format files next. You can then apply the latest translations (that is, your edited versions of the translations) to the UI files in the target language. You can regenerate any number of files from the output files set per target language.

1. Click the **Regenerate** icon next to the target language section. The **File upload** slider will open.
2. Zip the edited XLIFF files, and then click **Upload**. Don't change the XLIFF file name that DTS originally provided.
3. In the prompt, confirm the upload.
4. The **Request output** tab promptly refreshes the content. Expand the target language node you just regenerated to verify the **Modified** timestamp and then download the updated output files.
You can repeat the regeneration process as many times as you require.
This topic explains how to translate a documentation file for Microsoft Dynamics products and solutions.

Create a translation request

1. In Microsoft Dynamics Lifecycle Services (LCS), on the DTS dashboard, select Add to create a new translation request.

You can open the DTS dashboard either from the LCS home page or from within a project. For more information, see Accessing DTS.

2. Enter the required information for the request.

<table>
<thead>
<tr>
<th>FIELD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Request name</td>
<td>Enter a name for the request.</td>
</tr>
<tr>
<td>File type</td>
<td>Select Documentation.</td>
</tr>
<tr>
<td>Product name</td>
<td>Select a product name. If you accessed DTS from within an LCS project, this field is automatically filled in and is read-only.</td>
</tr>
<tr>
<td>Product version</td>
<td>Select a product version. If you accessed DTS from within an LCS project, this field shows the default product version information from the project. However, you can select a different version.</td>
</tr>
</tbody>
</table>
3. Select **Create**.
NOTE
To take advantage of the product-specific model that is trained on Microsoft Dynamics linguistic assets, you must select English – United States as either the source language or the target language. Here is an example.

<table>

</tr>
<tr>
<td>German</td>
<td>Japanese</td>
<td>Generic MT model</td>
</tr>
</tbody>
</table>

Upload files

Select the plus sign (+) in each section to open the File upload page.

Upload files to translate (Required)
Currently, only files in Microsoft Word (.docx) format are accepted for translation. Create a zip file that includes all the .docx files in the source language that you want to translate from. You can upload only one zip file. Note that DTS doesn’t change the source files that you upload. The source files are only used to create files in the corresponding target languages you requested.

Upload XLIFF or TMX translation memory files (Optional)
If you have a TM in Translation Memory eXchange (TMX) format from a previous DTS request, and/or if you have a XLIFF TM from UI file translation, you can attach those TMs so that they can be recycled in the new document that you’re submitting. Create a zip file that includes all the TM files. You can upload only one zip file. If you created the translation request for multiple target languages, you must select which target language the TM file is for.

With the translation memory file you are providing, you have an option to decide whether you want to create a custom MT system trained with it. This option may take longer time to complete the request. You must choose
Yes or No to be able to continue with the TM file upload.

After you've finished uploading file, select **Submit** to start the translation process.

After you submit the request, a new request ID is created on the DTS dashboard. If you submitted the request with multiple target languages, you will see each target language status is displayed in a separate line with the same request ID. Selecting a line on the dashboard will extend the dashboard window to the right to show the request summary information.

To view the request status, select a request ID link on the dashboard. The **Request status** tab shows the list of source files that you uploaded, together with a summary of the request information.

Note that the processing time depends on the number of requests that are in the DTS queue and the word count in the source files that you submit.

**After translation is completed**

When processing of your translation request is completed, you receive an email notification from DTS. You can then view the result on the **Request output** tab of the request details page. If your request was submitted for multiple target languages, there may be a difference between languages when each language process is done. Expand each language name to see the status.
For documentation translation requests, three types of output file are available after the translation process is completed:

- **For translation review** – Download this file to review and edit the translated document strings in a table view. The file shows the source and target languages segments side by side.

- **Translated native format** – Download this file if you don't intend to review or edit the translations, but intend to use the translated file as it is. This file has the same formatting style (title, headings, tables, and so on) as the source .docx file that you submitted, and it's ready to be used.

- **Translation memory** – Download this file to recycle these translations the next time that you submit a translation request that uses a newer version of the source document.

**Review and edit the translations**

DTS provides the translation review file in .docx format. You can download the file from the Request output tab of the request details page and open it in Word. The file provides a convenient table view, as shown in the following illustration. Therefore, you can easily compare the text in the source and target languages side by side. After you've finished reviewing the file, you must save it and upload it back to DTS to generate the updated .docx file output in the original formatting style that you submitted.

<table>
<thead>
<tr>
<th>Segment ID</th>
<th>Segment status</th>
<th>Source segment</th>
<th>Target segment</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Draft (0%)</td>
<td>&lt;109&gt;&lt;117&gt; &lt;110&gt; &lt;103&gt; Pre Go-live checklist &lt;/109&gt; &lt;/110&gt; &lt;/117&gt;</td>
<td>&lt;109&gt;&lt;117&gt;&lt;110&gt; &lt;103&gt; Avant mise en service liste de vérification &lt;/109&gt; &lt;/110&gt; &lt;/117&gt;</td>
</tr>
<tr>
<td>2</td>
<td>Draft (0%)</td>
<td>Customer:</td>
<td>Client :</td>
</tr>
<tr>

</tr>
<tr>
<td>6</td>
<td>Draft (0%)</td>
<td>Go-live date:</td>
<td>Date de mise en service :</td>
</tr>
<tr>
<td>7</td>
<td>Draft (0%)</td>
<td>DD-MM-YYYY</td>
<td>AAAA-MM-JJ</td>
</tr>
<tr>
<td>8</td>
<td>Draft (0%)</td>
<td>Dynamics 365 for Finance and Operations, Enterprise edition customers should complete a Pre-Go-live review with the Microsoft FastTrack team before requesting their production environment.</td>
<td>Dynamics 365 pour Finance and Operations, clients Édition entreprise doit remplir une révision live donné avant avec l'équipe Microsoft FastTrack avant de demander son environnement de production.</td>
</tr>
</tbody>
</table>

When you edit the .docx review file, note of the following guidelines:

- Edit only the text in the Target segment column.
- Don't add or remove rows.
- Don't change the order of the rows or columns.
- Don't add or remove the red tags. Most red tags represent formatting and styles.
- If you must move the red tags, be careful that you don't switch a start tag (for example, &lt;116&gt;) and its end tag (&lt;/116&gt;).

**Regenerate output files**

When you've finished reviewing and editing a .docx review file, you must regenerate the output file in the source document style. You can then apply the latest translations (that is, your edited versions of the translations) to the documentation files in the target language.

1. Click the Regenerate icon next to the target language section. It brings in the File upload slider.
2. Zip the edited .docx files, and then select Upload. Don't change the file names that DTS originally provided for the .docx review file.
3. You're prompted to confirm the upload action.
4. Once the regenerate is processed, the Request output tab refreshes the content. This process may take some time to complete.
You can repeat the regeneration process as many times as you require.

For more information about the Microsoft Dynamics 365 Translation Service (DTS), see Dynamics 365 Translation Service overview. For information about how to translate a user interface (UI) file, see Translate user interface files.
Microsoft Dynamics 365 Translation Service (DTS) uses a bilingual XML Localization Interchange File Format (XLIFF) file to store pairs of source languages and target languages. Because XLIFF is based on XML, you can open XLIFF files in any text editor. However, we recommend that you use XLIFF editors that are specifically designed to work with this format. For example, you can use the free Microsoft Multilingual Editor that is available in the Multilingual App Toolkit (MAT).

In DTS, you can obtain an XLIFF translation memory (TM) in two ways:

- **Run the Align tool** – When you have files that were previously translated, and you also have corresponding source files, you can use the Align tool to create an XLIFF TM. For more details, see the Creating a translation memory section later in this topic.
- **Complete a translation request** – When a DTS translation request is completed, it provides the XLIFF TMs as part of the request output. You can then use the files the next time that you submit a new translation request that includes the updated source files.

XLIFF files contain a series of translation units (TUs) that are extracted from the source files. The following illustration shows an example of a TU.

```
<trans-unit id="PRO39" translate="yes" xml:space="preserve">
  <source>Rebate</source>
  <target state="translated" state-qualifier="exact-match">リベート</target>
</trans-unit>
```

The following illustration shows the same TU (highlighted in blue) in the Multilingual Editor.

**State**

Each translation in the XLIFF file is associated with a state value. The state value that DTS assigns to each translation depends on the way that the string is translated. When an XLIFF TM is created by using the Align tool, all translations are marked as **Translated**, because the aligned TUs are produced from known good translations, such as a previous product version.
However, when the XLIFF files are generated through a translation request, two types of state values can be used:

- **Needs Review** – The string has been machine-translated.
- **Translated, Final, or Signed off** – The string has been recycled. The state value is inherited from the XLIFF TM.

During the post-editing process, you can immediately identify the strings that are marked as Needs Review. After you’ve finished reviewing those strings, you should mark them as Translated, Final, or Signed off, so that they can be used for recycling. Translations that are marked as Needs Review aren’t included for recycling. Inherited state values for recycled strings are helpful, because you won’t have to review the same string (that is, a string that has the same ID) again.

**Creating a translation memory**

If you have files that were previously translated, you can recycle the translated files for a newer version of the source files by creating a TM that uses XLIFF.

1. On the DTS dashboard, select the **Align** button to start the Align tool.

   ![Align tool image]

   **NOTE**
   
   - The Align tool currently supports only user interface (UI) files.
   - To start the Align tool, you might have to explicitly allow pop-up windows in your browser.

2. On the **Align** page, select the source language, the target language, and the files to align.

3. Select **Align** to complete the alignment. When the alignment is completed, a message summarizes the results.
To create the best XLIFF TM, make sure that the following conditions are met:

- Both the source file and the target file have the same number of resources.
- The resources are in the same order in both the source file and the target file.
- There are no empty strings. The following illustration shows examples of empty strings in the source and the target.

Empty strings are inherited by the XLIFF TM. If a **Rebate** string in the source has an empty string in the
Editing an XLIFF translation memory

We recommend that you use the free Multilingual Editor, or another XLIFF editor, to review and edit the translations in the XLIFF file that DTS provides. At a minimum, you should review the translations to verify that the translation output meets your product’s quality standards.

When you open an XLIFF file in the Multilingual Editor, it resembles the following illustration. If you encounter an error when you open the file, ignore the message, and select the **Strings** tab in the lower-left corner of the window.

Notice that there is a circle near the beginning of each line. The color of the circle indicates the state of the translation. DTS automatically assigns these states, depending on where the string came from.

- **Red circle** – The string was machine-translated. DTS assigns the **Needs Review** state.

Although the Align tool can resolve some of these issues, it’s easier if you prevent them before you see unexpected results in the output.

Review the aligned XLIFF file before you use it as a TM. TUs that have been reviewed should be marked as **Final** or **Signed off**, so that they aren’t mistaken for unreviewed TUs.
NOTE
The state value that is shown might differ slightly, depending on the XLIFF editor that you’re using.

- Yellow, green/yellow, or green circle – The string was recycled. DTS inherited the state from the XLIFF TM that was used in the request.

To verify the translations, you can apply a filter to show only strings that are in the Needs Review state.

Strings that have been reviewed should be marked as Translated, Final, or Signed off, so that they can be used for recycling. Translations that are marked as Needs Review aren’t included for recycling.

After you’ve finished editing the XLIFF TM, remember to have DTS regenerate the refreshed output file in the source format. For more information about how to regenerate the file, see Translate user interface files.
Microsoft Power Platform provides a suite of capabilities for Dynamics 365 applications via the Power Platform admin center. Today, Finance and Operations apps are not managed by the Power Platform admin center. However, over time more and more management capabilities will be migrated from Microsoft Dynamics Lifecycle Services (LCS) over to the admin center. In the interim, customers will be able to unlock features, such as dual-write functionality, virtual entities, add-ins, and more via Microsoft Power Platform integration functionality in LCS.

Prerequisite reading

To understand the architecture of Microsoft Power Platform, Dataverse, dual-write, and virtual entities for Finance and Operations apps, you must understand how they work. Therefore, the following documentation is a prerequisite:

- Administer Power Platform
- What is Dataverse?
- Tables in Dataverse
- Entity relationships overview
- Create and edit virtual tables that contain data from an external data source
- What is Power Apps portals?
- Overview of creating apps in Power Apps

Tools and services unlocked with Microsoft Power Platform integration

Together, virtual entities, dual-write, business events, and data events make up the shared data layer for the convergence of Finance and Operations apps and the Dataverse platform. They are complementary technologies that are intended to work together.

Virtual entities enable scenarios where access to Finance and Operations data from Microsoft Power Platform or native Dataverse apps is required. You can query that data, bind forms to it, and generally use the full power of Microsoft Power Platform against the full breadth of Finance and Operations apps. Data isn’t copied between systems. Instead, it’s accessed directly through the standard virtual entity infrastructure that Microsoft Power Platform technologies can already bind to. For more information, see Virtual entities overview.

Business events let you use Microsoft Power Platform to respond to events that are occurring in Finance and Operations apps. These events occur when a process is run in the application with business logic. Business events can be raised from any app, including Finance and Operations apps, and can be handled by Microsoft Power Platform business logic. This handling will often include querying or interacting with additional data through either native entities or virtual entities.

Data events, similar to business events, enable external applications to receive notifications from Finance and Operations apps when events occurs. Data events occur when there is a change to a record in the application data. External systems can react to notifications when a create, update, or delete (CUD) operation occurs in the data.
For a subset of scenarios, data must be physically copied between Finance and Operations apps and native Dataverse entities. These scenarios are for overlapping entities that already have a large amount of bound logic in both native Dataverse apps and Finance and Operations apps, so that the data must reside in the local database of each type of app. Although the number of these entities is relatively small, it includes some of the most important entities, such as Account/Customer, Company, Product, and Sales order. For these scenarios, dual-write enables near-real-time synchronous copying of data. This capability enables existing apps to continue to operate against local data, as designed, and also ensures that the corresponding overlapping entity is kept in sync. For more information, see the Dual-write home page.

Together, virtual entities, dual-write, business events, and data events let you build apps and business processes that span the boundaries between Finance and Operations apps and native Dataverse apps. Most apps and business processes will use either a combination of these three parts of the shared data layer or all of them. As always, extension and customization should reduce the amount of data that is copied between databases as much as possible, and should also optimize for the best possible user experience when these tools are used.

**Add-ins functionality**

Add-ins provide a way to extend the functionality of Finance and Operations apps. All add-ins are installed and managed via Lifecycle Services on the environment details page for sandbox and production-type environments. The metadata regarding which add-ins are installed and the configuration options for each add-in are stored in the Microsoft Dataverse database that is provisioned as part of the Microsoft Power Platform integration. Some add-ins also store business data in the Dataverse database. To learn more about available add-ins, see Add-ins overview.

**Typical scenarios and patterns that use dual-write**

Here are some typical scenarios that use dual-write.

**Customer service representatives can facilitate a change of address for Finance and Operations customers**

A customer relocates and wants to change their billing and shipping address information. This customer contacts a customer service representative and requests a change of address. The customer service representative takes the call and changes the customer’s billing and shipping address information.

<table>
<thead>
<tr>
<th>DECISION</th>
<th>INFORMATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is real-time data required?</td>
<td>Yes</td>
</tr>
<tr>
<td>Peak data volume</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Frequency</td>
<td>Ad hoc</td>
</tr>
</tbody>
</table>

**Recommended solution**

This scenario that involves near-real-time data synchronization is best implemented by using dual-write.

1. The customer’s information is sourced in a Finance and Operations app.
2. A customer calls customer service and asks to change their billing and shipping address information.
3. A customer service representative retrieves the customer’s record in Dynamics 365 Customer Service.
4. The customer service representative updates the billing and shipping addresses, and saves the data.
5. The new billing and shipping addresses are synced back to the Finance and Operations app in real time.

**Sales representatives can change customer credit limits without signing in to a Finance and Operations app**

A customer has a credit limit of $2,000 and wants to increase it to $5,000. This customer calls and requests the increase. The ticket is assigned to the sales department. The head of sales reviews the request, reviews the customer’s payment history, and determines that the customer is eligible for an increased credit limit. The head of sales approves the request and responds to the ticket. The customer receives an email about the approval of
the $5,000 credit limit.

<table>
<thead>
<tr>
<th>DECISION</th>
<th>INFORMATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is real-time data required?</td>
<td>Yes</td>
</tr>
<tr>
<td>Peak data volume</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Frequency</td>
<td>Ad hoc</td>
</tr>
</tbody>
</table>

**Recommended solution**

This scenario is best implemented by using dual-write.

1. A customer calls and wants to increase their credit limit from $2,000 to $5,000.
2. A customer support representative creates a ticket in Dynamics 365 Customer Service.
3. The ticket is assigned to the sales unit.
4. A sales representative from the sales unit reviews and approves the request.
5. The customer's credit limit is increased to $5,000 in Dynamics 365 Sales.
6. The credit limit in the Finance and Operations app is updated to $5,000.
7. The sales representative responds to the ticket and resolves it.
8. The customer receives an email about the increased credit limit.
The integration of Finance and Operations apps with Microsoft Power Platform can be enabled when you create a new Finance and Operations apps environment in Microsoft Dynamics Lifecycle Services (LCS). Alternatively, Microsoft Power Platform can be enabled in an existing Finance and Operations apps environment. For both options, you must complete the setup prerequisites.

Prerequisites for setting up the Microsoft Power Platform integration

The following list describes the prerequisites for setting up the Microsoft Power Platform integration.

- Make sure that at least one gigabyte (GB) of Microsoft Power Platform database storage capacity space is available for your tenant. If this space isn't available, the setup will fail. View your capacity in the Power Platform admin center.

- Identify your Finance and Operations apps environment administrator. You can find that information in the Environment details section.

- Validate the governance policy of your Microsoft Power Platform environment. To do this validation, you must have either the Global administrator role or the Power Platform administrator role.
  
  1. Sign in to the Power Platform admin center.
  2. Select Settings in the upper-right corner of the page to open the Power Platform settings pane.
For organizations that don’t allow everyone to create Microsoft Power Platform production environments, the Finance and Operations apps environment administrator account for your environment must be added to one of the following Microsoft Power Platform admin roles. To make this change, you must have the **Global administrator** role.

- Global admins
- Dynamics 365 admins
- Microsoft Power Platform admins

**NOTE**

The preceding roles might provide more permissions than the Finance and Operations apps environment administrator account requires. Therefore, a more limited role for this integration will eventually be added to Azure Active Directory (Azure AD). The new role won’t require any of the preceding roles. If you want to keep the administrator that has the least privileges, you can temporarily grant one of the preceding roles. Then, after the Microsoft Power Platform integration is set up, remove that role.

All users who create Microsoft Power Platform environments must be licensed. The Microsoft 365 admin center should be used to apply the **Dynamics 365 Unified Operations Plan** license, the **AX Enterprise** license, or an application-specific license such as **Dynamics 365 Finance** to the Finance and Operations apps environment administrator account.
Enable integration during environment deployment

When you set up a new Finance and Operations apps environment in LCS, the deployment wizard includes several sections where you can set values. One of those sections is named **Power Platform Integration**.

Follow these steps to configure the **Power Platform Integration** section.

1. Set the **Configure Power Platform Environment** option to **Yes**. Several additional settings become available.

2. In the **Power Platform template** field, select one of the following values:
   - **Dynamics 365 Standard** – This basic template is applicable to all Finance and Operations apps environments. Select this value if you don’t require a more specific template.
   - **Project Operations** – This template is specific to the Dynamics 365 Project Operations scenario. This value is available only if your tenant has licenses and entitlement for Project Operations.

3. If you’re deploying a DevTest or cloud-hosted environment, the **Environment Type** field is available. There, you can select the type of Dataverse environment that is created and linked. Otherwise, by default, the environment type is set to **Sandbox** for Tier 2 through Tier 5 acceptance test environments and **Production** for production environments.

4. Select **Agree** to agree to the terms and conditions of the integration.

**IMPORTANT**

The **language** and **currency** values of the Dataverse environment that is created and linked to your Finance and Operations apps environment are automatically determined, based on the physical address of your Azure AD tenant. For example, if the address is in Redmond, Washington, USA, the language will be English by default, and the currency will be US dollars (USD).

If you require values that differ from the default values, contact Microsoft support. We can help link an existing Dataverse environment that you manually provision to the Finance and Operations apps environment. Eventually, fields for the language and currency will be added as setup options, so that you can manually set them or accept the default values.

Enable integration after environment deployment

If the Microsoft Power Platform integration isn’t enabled during deployment of the Finance and Operations apps environment, you can enable it in LCS after deployment. To do the setup after the Finance and Operations apps environment has been deployed, follow these steps.
1. After the Finance and Operations apps environment has been deployed through LCS, open the **Environment details** page in LCS.

2. In the **Power Platform integration** section, select **Setup**.

   ![Lifecycle Services](image.png)

   **Manage environment**

   **Power Platform Integration**

   Expand your environment’s capabilities through Power Platform integration. Unlock features such as Dual-write, add-ins, and all the capabilities of Microsoft Dataverse.

   **POWER PLATFORM ENVIRONMENT INFORMATION**

   - **Setup**

   **ENVIRONMENT ADD-INS**

   Power platform environment must be setup to install add-ins.

3. In the **Power Platform environment setup** dialog box, agree to the terms and conditions, and then select **Setup**.

   ![NOTE](image.png)

   **NOTE**

   A Dataverse-based environment will now be provisioned in the Power Platform admin center. The environment typically requires 1 GB of database storage capacity and will have the same name as your Finance and Operations apps environment. Dual-write platform-level components will be installed, but dual-write application components won’t be set up or enabled. Those actions are separate.

4. When you receive a message that states that the Microsoft Power Platform environment is being provisioned, select **OK**.

   The **Power Platform integration** section of the **Environment details** page now shows a message that states that the Microsoft Power Platform environment is being provisioned.

5. After a few minutes, refresh the **Environment details** page.

6. In the **Power Platform integration** section, notice that the value of the **Status** field is **Environment setup is in progress**.

   Typically, the setup takes between 60 and 90 minutes.

   After the Dataverse environment is provisioned, the **Install a new add-in** and **Dual-write application** buttons become available in the **Power Platform integration** section.
Enable integration with an existing, selected Microsoft Power Platform environment

When you enable the Microsoft Power Platform integration for a Finance and Operations apps environment in LCS, either during or after deployment, the process creates a new Dataverse-enabled Microsoft Power Platform environment and links the Finance and Operations apps environment to the new Microsoft Power Platform environment. However, you might want to enable integration by linking your Finance and Operations apps environment to an existing Microsoft Power Platform environment rather than the environment created automatically during deployment. The option to select the Power Platform environment with which to enable the Power Platform integration isn't currently available in LCS.

How the Power Platform integration is enabled for existing environments depends on the number of Power Platform environments that are linked to the Finance and Operations apps environment. Before you enable the Power Platform integration, there are multiple ways in which a Finance and Operations apps environment can...
be considered linked to a Power Platform environment:

- **Deployment link**: During the deployment of a new Finance and Operations environment, even when the option to enable the Power Platform integration is not selected, a new Power Platform environment is created and linked to the Finance and Operations environment. You can see this link in the Finance and Operations URL field of the environment details for the new Power Platform environment in the Power Platform admin center.

- **Dual-write**: The option is available in the dual-write configuration to create a link to a Dataverse environment in any Power Platform environment on the tenant.

- **Virtual entities**: The virtual entity configuration in the Power Platform environment allows you to select the Finance and Operations environment.

These three configurations won't necessarily link the Finance and Operations apps environment to the same Power Platform environment. There are two scenarios for enabling the Power Platform integration with an existing Microsoft Power Platform environment:

- **Single Power Platform environment**: In this scenario, the Finance and Operations apps environment has matched links to a single Power Platform environment. If dual-write and/or virtual entities have been configured for the Finance and Operations apps environment, they are configured to link to the same Power Platform environment created during deployment of the Finance and Operations apps environment.

- **Multiple Power Platform environments**: There is a linking mismatch among existing links between the Finance and Operations apps environment and more than one Power Platform environment.

**Finance and Operations apps connected to a single Microsoft Power Platform environment**

If the Finance and Operations apps environment is configured with links to a single Microsoft Power Platform environment, these environments are identified as a one-to-one linking. For these environments, in Finance and Operations apps version 10.0.22 (Platform update 46) a one-to-one linked environment will automatically be updated to enable the full Microsoft Power Platform integration for the Finance and Operations apps environment.

In version 10.0.22, you can verify that the Microsoft Power Platform integration was automatically enabled by viewing the Power Platform Integration section of the Environment details page for the Finance and Operations apps environment in LCS. If the integration was successfully enabled, the Environment name field will show the name of the integrated Microsoft Power Platform environment, and the Status field is set to Setup completed successfully.

**Finance and Operations apps connected to multiple Microsoft Power Platform environments**

If a Finance and Operations apps environment has been manually linked to multiple Microsoft Power Platform environments, the process of enabling the Microsoft Power Platform integration for the environment can't be automated. The system can't automatically determine to which Power Platform environment the Finance and Operations apps environment should be linked for the Power Platform integration.

**NOTE**

The Microsoft Power Platform integration will automatically be enabled for Finance and Operations apps environments that are already connected to a single Microsoft Power Platform environment and that already use business events functionality. However, these environments won't be able to use the new business events and data events functionality starting in release 10.0.22. The business events endpoints that are already used in these environments will be migrated to the Dataverse platform in version 10.0.23. At that point, the new business events and data events functionality will become available in the environments. Until then, business events will continue to work as they are currently configured in the environment.

For more information about the new business events and data events functionality that will be delayed for these environments until the migration is completed, see Finance and Operations business events in Dataverse and Finance and Operations CUD events in Dataverse in the 2021 release wave 2 plan.
There are two options to enable the Power Platform integration for a Finance and Operations environment that has links to multiple Power Platform environments:

- Reconfigure your dual-write and/or virtual entity solutions to link the Finance and Operations apps environment to the Power Platform environment created at deployment. When all links are configured for the single Power Platform environment, you can enable the Power Platform integration in LCS following the steps outlined in the Enable integration after environment deployment section above. This is the preferred solution because it can be managed without Microsoft support.
- To enable the Power Platform integration with a linked Power Platform environment other than the Power Platform environment created during deployment of the Finance and Operations environment, either work with your FastTrack solution architect or contact Microsoft Support to enable the Power Platform integration with a selected environment.

For more information about dual-write configuration options, see Linking mismatch.

Enable the integration for cloud-hosted development environments

You can manually enable the Microsoft Power Platform integration for cloud-hosted development environments by completing the procedures in this section. For information about how to deploy cloud development environments, see Deploy and access development environments.

Register an application in the Azure portal

<table>
<thead>
<tr>
<th>IMPORTANT</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Azure AD application must be created on the same tenant as the Finance and Operations app.</td>
</tr>
</tbody>
</table>

1. Open the Azure portal.
2. Go to Azure Active Directory > App registrations.
3. Select New registration, and enter the following information:
   - Name – Enter a unique name.
   - Account type – Select Accounts in any organizational directory (Any Azure AD directory - Multitenant).
   - Redirect URI – Leave this field blank.
4. Select Register.
5. Make a note of the Application (client) ID value. You will need this value later.
6. Create a symmetric key for the application.
   a. Select Certificates & secrets in the left navigation pane for the new app registration.
   b. Select New client secret.
   c. Enter a description and an expiration date.
   d. Select Save.
   e. Copy the key in the Value field that is created. You will need this key value later.

Add the Azure AD application as a Microsoft Power Platform user

After the Azure AD application has been created in the Azure portal, it must be added as a Microsoft Power Platform application user.

1. In the Power Platform admin center, create the application user by following the steps in Create an application user.
2. In the step where you select security roles to add for the application user, select **Finance and Operations Integration User**.

**Grant app permissions in Finance and Operations apps**

Dataverse will use the Azure AD application that you created to call Finance and Operations apps. Therefore, the application must be trusted by Finance and Operations apps and associated with a user account that has the appropriate rights.

1. In Finance and Operations apps, go to **System administration > Setup > Azure Active Directory applications**.

2. Select **New** to add a row to the grid, and enter the following information:

   - **Client ID** – Enter the **Application (client) ID** value of the Azure AD application that you created earlier.
   - **Name** – Enter **Dataverse Integration** (or another name that you will recognize for the integration).
   - **User ID** – Select **PowerPlatformApp**.

**NOTE**

The **PowerPlatformApp** user that is available has the appropriate permissions for Dataverse integrations with Finance and Operations apps. However, if this user doesn't exist, or if you want to use a different application user account, you can create or use any other user that has the following roles: **Business events security role**, **Dataverse Virtual entity application**, **Dataverse Virtual entity anonymous user**, and **Dataverse Virtual entity authenticated user**.

**Configure Finance and Operations apps to use the Azure AD application to connect to Dataverse**

2. Copy the following Windows PowerShell script, and save it to the virtual machine (VM) for the Finance and Operations environment as a .ps1 file.

```powershell
param(
    [Parameter(Mandatory = $false)]
    [switch]$Relaunched
)

$isRelaunched = $false
if ($PSBoundParameters.ContainsKey("Relaunched"))
{
    $isRelaunched = $Relaunched.IsPresent
}
{
    # Relaunch as an elevated process:
    Start-Process powershell.exe "-File", (""{0}"" -f $MyInvocation.MyCommand.Path), "-Relaunched" -Verb RunAs
    exit
}

$aosWebsiteName = "AOSService"

function Get-AosWebSitePhysicalPath()
{
    if (Get-Service W3SVC | Where-Object status -ne 'Running')
    {
        #IIS service is not running, starting IIS Service.
        Start-Service W3SVC
    }
```

```powershell
```
```
$webSitePhysicalPath = (Get-Website | Where-Object { $_.Name -eq $aosWebsiteName }).PhysicalPath

return $webSitePhysicalPath

function Set-WebConfigValue($Key, [string]$Value)
{
    $webroot = Get-AosWebSitePhysicalPath
    $webConfigPath = Join-Path $webroot "web.config"
    if (-not (Test-Path $webConfigPath))
    {
        Throw "Unable to find web.config file at '" + $(webConfigPath) + "'..."
    }
    $appSettingNode = $webConfigDocument.SelectSingleNode("/configuration/appSettings/add[@key='$($Key)']")
    if ($null -ne $appSettingNode)
    {
        Write-Host "Updating key '" + $(Key) + "' to value '" + $(Value) + "'..."
        $appSettingNode.Value = [string]$Value
    }
    else
    {
        Write-Host "Inserting new key '" + $(Key) + "' with value '" + $(Value) + "'..."
        $ns = New-Object System.Xml.XmlNamespaceManager($webConfigDocument.NameTable)
        $addElement = $webConfigDocument.CreateElement("add")
        $addElement.SetAttribute("key", $Key)
        $addElement.SetAttribute("value", $Value)
        $appSettings = $webConfigDocument.SelectSingleNode("/ns:appSettings", $ns)
        $appSettings.AppendChild($addElement) | Out-Null
    }
    $webConfigDocument.Save($webConfigPath)
    Write-Host
}

function Confirm-ValueOfType($Value, $Type)
{
    if ($Type -eq "Uri")
    {
        try
        {
            New-Object System.Uri $Value | Out-Null
        }
        catch
        {
            Throw "Cannot parse '" + $(Value) + "' as a URL: " + $( $_ )
        }
    } elseif ($Type -eq "Guid")
    {
        try
        {
            [Guid]::Parse($Value) | Out-Null
        }
        catch
        {
            Throw "Cannot parse '" + $(Value) + "' as a guid: " + $( $_ )
        }
    } elseif ($Type -eq "String")
    {
        if ([string]::IsNullOrEmpty($Value))
        {
            Throw "String value cannot be empty."
        }
    }
function Update-WebConfigValueFromHost($Key, $Prompt, $Type)
{
    $value = Read-Host -Prompt $Prompt
    Confirm-ValueOfType -Value $value -Type $Type
    Set-WebConfigValue -Key $Key -Value $value
}

function Enable-Flight($FlightName)
{
    Write-Verbose "Enabling flight '$($FlightName)'..."
    $webroot = Get-AosWebSitePhysicalPath -ErrorAction stop
    $webrootBinPath = Join-Path $webroot "bin"
    $environmentDllPath = Join-Path $webrootBinPath 'Microsoft.Dynamics.ApplicationPlatform.Environment.dll'
    Add-Type -Path $environmentDllPath
    $ServerName = $config.DataAccess.DbServer
    $DatabaseName = $config.DataAccess.Database
    $UserId = $config.DataAccess.SqlUser
    $Password = $config.DataAccess.SqlPwd
    $EnableFlightQuery = "DECLARE @flightName NVARCHAR(100) = '$($FlightName)';
    IF NOT EXISTS (SELECT TOP 1 1 FROM SysFlighting WHERE flightName = @flightName)
    INSERT INTO SYSFLIGHTING(FLIGHTNAME, ENABLED, FLIGHTSERVICEID, PARTITION)
    SELECT @flightName, 1, 12719367, RECID FROM DBO.[PARTITIONS];
    ELSE
    UPDATE SysFlighting SET enabled = 1, flightServiceId = 12719367 WHERE flightName = @flightName;"
    Invoke-Sqlcmd -ServerInstance $ServerName -Database $DatabaseName -Username $UserId -Password $Password -Query $EnableFlightQuery
    Write-Verbose "Flight '$($FlightName)' has been enabled."
}

function Test-Settings()
{
    $cdsApiPath = "accounts";
    Write-Host "Testing setup by calling API '$($cdsApiPath)'..."
    $webroot = Get-AosWebSitePhysicalPath -ErrorAction stop
    $webrootBinPath = Join-Path $webroot "bin"
    $httpCommunicationDllPath = Join-Path $webrootBinPath "Microsoft.Dynamics.HttpCommunication.dll"
    Add-Type -Path $httpCommunicationDllPath
    $ServerName = $config.DataAccess.DbServer
    $DatabaseName = $config.DataAccess.Database
    $UserId = $config.DataAccess.SqlUser
    $Password = $config.DataAccess.SqlPwd
    $enableFlightQuery = "DECLARE @flightName NVARCHAR(100) = '$($FlightName)';
    IF NOT EXISTS (SELECT TOP 1 1 FROM SysFlighting WHERE flightName = @flightName)
    INSERT INTO SYSFLIGHTING(FLIGHTNAME, ENABLED, FLIGHTSERVICEID, PARTITION)
    SELECT @flightName, 1, 12719367, RECID FROM DBO.[PARTITIONS];
    ELSE
    UPDATE SysFlighting SET enabled = 1, flightServiceId = 12719367 WHERE flightName = @flightName;"
    Invoke-Sqlcmd -ServerInstance $ServerName -Database $DatabaseName -Username $UserId -Password $Password -Query $enableFlightQuery
    Write-Verbose "Flight '$($FlightName)' has been enabled."
}

3. Run the script in Windows PowerShell, and follow the instructions. You will enter the following information:

- **Dataverse Organization URL** – Enter the URL that is used to access Dataverse. For example, enter [https://contoso.crm.dynamics.com](https://contoso.crm.dynamics.com). You can find this URL in the Environment URL field in the Details section of the environment details in the Power Platform admin center.

- **Dataverse Organization ID** – You can find this ID in the Organization ID field in the Details section of the environment details in the Power Platform admin center.

- **Dataverse AAD Tenant domain** – Enter the primary domain of the Azure AD tenant that is used by Dataverse. You can find this domain in the Domain field for the directory on the Portal settings page in the Azure portal. Typically, it’s also the domain segment of the administrator’s email address. For example, if the email address is `admin@contoso.onmicrosoft.com`, the domain is `contoso.onmicrosoft.com`.

- **Dataverse AAD app ID** – Enter the Application (client) ID value of the Azure AD application that you created earlier.

- **Dataverse AAD app secret** – Enter the secret key value that was created earlier for the Azure AD apps.
Troubleshooting the setup

Setup can fail at various stages of the deployment of the Dataverse-based environment.

Any time that the setup fails, an error message is shown. The following illustration shows an example of the error message for a dual-write setup failure.

![Error message for dual-write setup failure](image)

Based on the error message, you might have to address licensing or capacity issues. After these issues have been fixed, you can select **Resume** in the **Power Platform integration** section of the **Environment details** page in LCS to finish the setup.
Finance and Operations apps and Microsoft Power Platform maintain separate user security. Users must have appropriate permissions in each environment to access Finance and Operations apps resources through Microsoft Power Platform. User setup can be simplified by synchronizing users between the two environments.

User provisioning

Creating Finance and Operations apps users in Microsoft Power Platform

There are three ways to automate the creation of Finance and Operations apps users in the Microsoft Power Platform environment:

- When a new Microsoft Power Platform environment is created as a linked environment that is linked to a Finance and Operations apps environment, all active users that are created in the Microsoft 365 admin center and that the Dynamics 365 Finance license is assigned to are automatically added as users in the new Microsoft Power Platform environment. For more information about how to create linked environments, see Enable the Microsoft Power Platform integration.

- When a new user is created in the Microsoft 365 admin center, and the Dynamics 365 Finance license is assigned, the new user is automatically created as a user in Microsoft Power Platform environments that are linked to a Finance and Operations apps environment. The process of creating the new user in Microsoft Power Platform can take up to an hour.

- If a user that the Dynamics 365 Finance license is assigned to signs in to the Microsoft Power Platform environment before user synchronization occurs, the user record is created when the Microsoft Power Platform environment is first accessed.

The creation of Finance and Operations apps users in linked Microsoft Power Platform environments can be automated. However, you can also add Finance and Operations apps users directly in Microsoft Power Platform by following the steps in Add users to an environment that has a Dataverse database.

Creating Microsoft Power Platform users in Finance and Operations apps

Administrators can manually import Microsoft Power Platform users into Finance and Operations apps from Azure Active Directory (Azure AD). To import users from Azure AD, select Import users in Finance and Operations apps. For more information, see Import new users from Azure AD.

Security model

Microsoft Power Platform users who work in Dataverse can interact with Finance and Operations apps entities through virtual entities. They can also receive business events that are triggered by user actions in Finance and Operations apps. To interact with virtual entities in Dataverse, a user requires access to the virtual entity metadata. When a transaction is performed in Dataverse, a virtual entity call is made to Finance and Operations apps. There, the call authorizes the user's request by validating against the user's security role and privileges that are defined in Finance and Operations apps.

For more information about Dataverse virtual entity interaction and the Finance and Operations apps security model, see Architecture.

Security roles in Microsoft Power Platform

When users who have the Dynamics 365 Finance license are automatically created as users in Microsoft Power Platform, both the Finance and Operations Basic User security role and the Environment Maker security role are automatically assigned to the user.
security role are automatically assigned to the Microsoft Power Platform users.

- **Finance and Operations Basic User** – This security role allows the user to access and update virtual entities and business events. When a virtual entity or business event is activated in the Dataverse environment, the virtual entity or business event privileges are automatically granted to the security role.

- **Environment Maker** – This security role allows the user to create apps in Power Apps and flows in Power Automate.

For information about how to manually assign security roles to Microsoft Power Platform users in the Power Platform admin center, see [Assign a security role to a user](#).

### Security roles in Finance and Operations apps

The security roles that are assigned to a user in Finance and Operations apps depend on the system access that the user requires to perform their assigned duties and responsibilities. The security roles in Finance and Operations apps determine the application data that a user has access to. A user can't access data through the Microsoft Power Platform integration if the user's assigned security roles in Finance and Operations apps don't grant permissions to the data.

The security role for Finance and Operations apps must be manually added by the system administrator. Different security roles can be assigned to a user in Finance and Operations apps.

Dual-write is an out-of-box infrastructure that provides near-real-time interaction between customer engagement apps in Microsoft Dynamics 365 and Finance and Operations apps. To get started with dual-write, see the Dual-write home page.

November 2021 release of party and global address book

The November 2021 release of the Dual-write Party and Global Address Book Solutions 3.3.0.5 contains the following features and bug fixes.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single view for party</td>
<td>We are providing a new form to access Party data. The Party form provides the capability to view and manage party records along with all the associated customers, contacts, and vendors and their postal addresses and electronic addresses from a single form.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>On the Accounts form, postal address updates from the Summary tab do not synchronize, which causes a data mismatch between Microsoft Dataverse and Finance and Operations apps.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>When an electronic address is changed from non-primary to primary, the updates to telephone extension/description fields does not synchronize from msdyn_partyelectronicaddress to Contact table.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Error while updating the Gender field on a Contact record to &quot;non-specific&quot; in Finance and Operations apps.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>In Finance and Operations apps, during address creation, when a second address is marked as primary and saved, the IsPrimary value change does not reflect in Dataverse.</td>
<td>General availability</td>
</tr>
</tbody>
</table>

September 2021 release of party and global address book

The September 2021 hotfix release of the Dual-write Party and Global Address Book Solutions 3.1.0.4 is based on Dual-write core solution version 1.0.29.

This release contains bug fixes listed in the following table.
**FEATURE** | **DESCRIPTION** | **STATUS**
--- | --- | ---
Bug fix | Some client APIs have been deprecated and replaced with new APIs. The JavaScript code has been upgraded to use the new client APIs. | General availability

Bug fix | Portals registration using email address fails when last name is not supplied. | General availability

Bug fix | Unable to create a new postal address for a vendor. | General availability

**August 2021 release**

The August 2021 release of Dual-write application orchestration solution version 2.3.0.15 is based on Dual-write core solution version 1.0.29.

This release contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bug fix</td>
<td>Fixes the case where dual-write alerts fail to send.</td>
<td>General availability</td>
</tr>
<tr>
<td>System tables</td>
<td>Adds support for enabling dual-write for system tables.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Some client APIs have been deprecated and replaced with new APIs. The JavaScript code in the dual-write orchestration package has been upgraded to use the new client APIs.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Because dual-write doesn’t support offline mode, the company name does not automatically contain a default value. You must select the company manually.</td>
<td>General availability</td>

</tbody>
</table>

This release includes following map changes.

- [CDS sales quotation lines] - [quotedetails] map version 1.0.0.1
- [CDS sales order lines] - [salesorderdetails] map version 1.0.0.1
- [Vendors V2] - [msdyn_vendors] map version 1.0.0.3
- [Vendor payment method] - [msdyn_vendorpaymentmethods] map version 1.0.0.1

**August 2021 release of party and global address book**

The August 2021 release of the Dual-write Party and Global Address Book Solutions 3.1.0.2 is based on Dual-write core solution version 1.0.29.

This release contains features and bug fixes listed in the following table.
### July 2021 release

The July 2021 hotfix release of Dual-write application orchestration solution version is based on Dual-write core solution version 1.0.28.

This release contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bug fix</td>
<td>Improved performance when more than 20 legal entities are enabled for dual-write.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Fixed issue with Is primary setting on postal address.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Fill the contact information on Contact for customer or vendor upon party association on main form.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Full name of contact with IsCustomer=Yes or IsVendor=Yes is blank during initial sync and live sync.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Make the country/region field required on both postal address table and customer address table.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Identify a phone number as mobile.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Update the display name from Parties Electronic Addresses table to Party Electronic Addresses table.</td>
<td>General availability</td>
</tr>
<tr>
<td>Party Electronic Address</td>
<td>Synchronize primary electronic address data from lead qualification process, account, and contact creation process to Party Electronic Addresses, and vice versa.</td>
<td>General availability</td>
</tr>
</tbody>
</table>

### June 2021 release

The June 2021 hotfix release ofDual-write application orchestration solution version 2.2.2.98 is based on Dual-write core solution version 1.0.27.

This release contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tracing</td>
<td>Logs basic transaction properties to a remote database for use in analytics and error detection.</td>
<td>General availability</td>

**Map instructions**

Follow these steps to apply the new maps:

1. Apply the latest map version 1.0.0.2 for CDS Postal address history V2 (msdyn_postaladdresses) mapping.
2. Apply the latest map version for Contacts V2 (msdyn_contactforparties) mapping.
3. Run the initial sync of the CDS Party postal address locations (msdyn_partypostaladdresses) mapping twice to make sure that there is no loss of address records in Customer Address table due to concurrent address updates.

**April 2021 release**

The April 2021 hotfix release of the Dual-write application orchestration solution version 2.2.2.60 is based on Dual-write core solution version 1.0.25.

This release contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>

<tr>
<td>Bug fix</td>
<td>A note without a description throws error.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>In Finance and Operations apps, running the “Calculate Sales Totals” batch job updates all orders modified within last 24 hours and fixes the totals regardless of the status of the order for example, canceled or fulfilled. That action triggers a re-cancellation or re-fulfillment causing a conflict error.</td>
<td>General availability</td>
</tr>
</tbody>
</table>

February 2021 release

The February 2021 release of the Dual-write application orchestration solution version 2.2.2.23 is based on Dual-write core solution version 1.0.24 and version 10.0.16 (10.0.689.10004) or newer of Finance and Operations apps and version 9.1.0000.11732 or newer of Dataverse.

This release contains the features and bug fixes listed in the following table.
<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Commerce price engine for sales quotations</td>
<td>Get pricing for sales quotations using commerce price engine.</td>
<td>General availability</td>
</tr>
<tr>
<td>Notes integration</td>
<td>Notes are integrated between customer engagement apps and Finance and Operations applications for customers, vendors, sales orders, and purchase orders.</td>
<td>General availability</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you don't need notes integration, do not install or upgrade to Dual-write application orchestration solution version 2.2.2.23 or later. If you install the update, you won't be able to uninstall the notes feature.

**January 2021 release**

The January 2021 release of the Dual-write application orchestration solution version 2.2.1.30 is based on Dual-write core solution version 1.0.24 and version 10.0.14 of Finance and Operations apps.

This release contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bug fix</td>
<td>French-localized strings in the user interface exceeded the maximum limit of 100 characters.</td>

Bug fix

Fixes the bug where an unrecognized tag configuration would cause dual-write execution to be skipped

General availability

September 2020 release

The September 2020 release of the Dual-write application orchestration solution version 2.0.777.493 is based on Dual-write core solution version 1.0.21.

The September 2020 release contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Lead qualification process in Sales is now company striped

Dynamics 365 Sales users can create a lead, qualify the lead to an opportunity, convert an opportunity into a quote, activate a quote, and create an order. This process was broken in dual-write due to lack of company striping on the Lead entity. We implemented company striping on the Lead entity, which cascades the company to the underlying Account and Opportunity tables. Thus the application behavior is restored to support the process. During the Lead qualification process, the Contact entity isn't company striped. This design supports the Party entity model that is due in October 2020. To learn about the Party and GlobalAddressBook model for dual-write, join the dual-write Yammer group.

### Map state transitions from Order to SalesOrder

The Order form in Dynamics 365 Sales is always set to Active. To create state transitions from Order in Dynamics 365 Sales to SalesOrder in Dynamics 365 Supply Chain Management, we introduced the ProcessingStatus column.

### Money to decimal data type conversion

Dataverse environments are limited to 4 decimal places for currency and 10 decimal places for exchange rates. Finance and Operations apps support more decimal places than Dataverse. You can now opt in to extend the decimal support in Dataverse to help ensure there’s no loss of decimal place data when using dual-write.

### Security role for company and currency exchange

Company and currency exchange tables are global in nature and all dual-write users require read access to these 2 tables. To simplify the experience, we’ve added a new security role named dual-write app user. Each dual-write user must be added to this security role.

### Security role for setup

Adds the Dual-write Runtime User security role. This role allows non-administrator users to create rows that are set up for dual-write. This feature is part of Dual-write core solution 10.0.21.

### Tracing

Internal column added for use in tracing. This feature is part of Dual-write core solution 10.0.21.
<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bug fix</td>
<td>Fixes issues where dual-write fails because of a mismatch between the plugin and the destination environments. This fix is part of Dual-write core solution 10.0.21.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Support to ensure that unused plugins are deleted. This fix is part of Dual-write core solution 10.0.21.</td>
<td>General availability</td>
</tr>
</tbody>
</table>

### August 2020 release

The August 2020 release of the dual-write orchestration package contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage multiple table maps</td>
<td>As part of day-to-day operations, you might need to bulk handle table maps. For example, you might want to simultaneously enable or pause a set of table maps. Instead of doing this one-by-one, which is cumbersome and time consuming, you can now enable, pause, resume, or stop more than one table map at the same time in the dual-write list page.</td>
<td>General availability</td>
</tr>
<tr>
<td>Bug fix</td>
<td>Fixes issues where rows would be skipped in certain cases during project execution. This fix is part of Dual-write core solution version 10.0.19.</td>
<td>General availability</td>
</tr>
</tbody>
</table>

### June 2020 release

The June 2020 release of the dual-write orchestration package contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Edit legal entity after setup</td>
<td>The company or legal entity list isn’t static and is constantly changing. You might need to add new companies, for example, during a phased rollout or acquisition. Previously, you couldn’t add a company or legal entity without system downtime. During this downtime, you would have to unlink and relink your environment. That can be expensive, especially if you have pre-existing data. With this feature, you can add a company in a live environment without having to unlink and relink.</td>
<td>General availability</td>
</tr>
</tbody>
</table>
May 2020 release

The May 2020 release of the dual-write orchestration package (version 2.0.777.353) contains the features and bug fixes listed in the following table.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Look up on-hand inventory</td>
<td>Ability to look up on-hand inventory and available-to-promise dates on forms in customer engagement apps.</td>
<td>General availability</td>
</tr>
<tr>
<td>Unit conversions</td>
<td>When unit conversions occur in a Finance and Operations app at the quote line and order line, the customer engagement app honors the unit conversion and reflects the respective changes to unit and price in the customer engagement app quote detail and order detail.</td>
<td>General availability</td>
</tr>
<tr>
<td>Currency change restriction</td>
<td>When you try to change the currency in a Finance and Operations app for an existing quote or order, the change fails.</td>
<td>General availability</td>
</tr>
<tr>
<td>Parity in <strong>Account</strong> and <strong>Contact</strong> forms</td>
<td>Bring attribute parity in <strong>Account</strong> and <strong>Contact</strong> forms in customer engagement apps for B2B and B2C customers.</td>
<td>General availability</td>
</tr>
<tr>
<td>No address duplication</td>
<td>Don’t duplicate an address in a Finance and Operations app when there’s a create or update action on a customer engagement app quote or order.</td>
<td>General availability</td>
</tr>
<tr>
<td><strong>SalesTaxGroup</strong> support</td>
<td>Support for <strong>SalesTaxGroup</strong> in <strong>Account</strong> and <strong>Contact</strong> forms for business-to-business (B2B) and business-to-consumer (B2C) customers.</td>
<td>General availability</td>
</tr>
<tr>
<td>Create sellable contacts</td>
<td>Allow creation of a sellable contact using the <strong>Quick Create: Contact</strong> form in customer engagement apps.</td>
<td>General availability</td>
</tr>
<tr>
<td>Quote and order creation</td>
<td>Enable quote and order creation for B2C customers.</td>
<td>General availability</td>
</tr>
<tr>
<td>Removal of tenant admin-level consent requirement</td>
<td>Until now, before you could enable dual-write, a tenant admin needed to explicitly give consent to the applications. This wasn’t always practical and required additional approval, which can be time consuming. With this feature, we removed this prerequisite and the need for explicitly giving consent to the applications.</td>
<td>General availability</td>
</tr>
</tbody>
</table>
### Force unlink dual-write environment

Previously, while testing dual-write, you had to disable all the table maps before unlinking a dual-write environment. This seemed cumbersome and sometimes not possible if one of the environments wasn't available. This new feature provides a quick way to unlink your test and trial environments.

<table>
<thead>
<tr>
<th>FEATURE</th>
<th>DESCRIPTION</th>

<td>General availability</td>
</tr>
</tbody>
</table>
What is dual-write?

Dual-write is an out-of-box infrastructure that provides near-real-time interaction between customer engagement apps and Finance and Operations apps. When data about customers, products, people, and operations flows beyond application boundaries, all departments in an organization are empowered.

Dual-write provides tightly coupled, bidirectional integration between Finance and Operations apps and Dataverse. Any data change in Finance and Operations apps causes writes to Dataverse, and any data change in Dataverse causes writes to Finance and Operations apps. This automated data flow provides an integrated user experience across the apps.

Dual-write has two aspects: an infrastructure aspect and an application aspect.

**Infrastructure**

The dual-write infrastructure is extensible and reliable, and includes the following key features:

- Synchronous and bidirectional data flow between applications
- Synchronization, together with play, pause, and catchup modes to support the system during online and offline/asynchronous modes.
- Ability to sync initial data between the applications
- Combined view of activity and error logs for data admins
- Ability to configure custom alerts and thresholds, and to subscribe to notifications
- Intuitive user interface (UI) for filtering and transformations
- Ability to set and view table dependencies and relationships
- Extensibility for both standard and custom tables and maps
- Reliable application lifecycle management
- Out-of-box setup experience for new customers

**Application**

Dual-write creates a mapping between concepts in Finance and Operations apps and concepts in customer engagement apps. This integration supports the following scenarios:

- Integrated customer master
- Access to customer loyalty cards and reward points
- Unified product mastering experience
- Awareness of organization hierarchy
- Integrated vendor master
- Access to finance and tax reference data
- On-demand price engine experience
- Integrated prospect-to-cash experience
- Ability to serve both in-house assets and customer assets through field agents
- Integrated procure-to-pay experience
- Integrated activities and notes for customer data and documents
- Ability to look up on-hand inventory availability and details
- Project-to-cash experience
- Ability to handle multiple addresses and roles through the party concept

Top reasons to use dual-write

Dual-write provides data integration across Microsoft Dynamics 365 applications. This robust framework links environments and enables different business applications to work together. Here are the top reasons why you should use dual-write:

- Dual-write provides tightly coupled, near-real-time, and bidirectional integration between finance and operations apps and customer engagement apps. This integration makes Microsoft Dynamics 365 the one-stop shop for all your business solutions. Customers who use Dynamics 365 Finance and Dynamics 365 Supply Chain Management, but who use non-Microsoft solutions for customer relationship management (CRM), are moving toward Dynamics 365 for its dual-write support.
- Data from customers, products, operations, projects, and the Internet of Things (IoT) automatically flows to Dataverse through dual-write. This connection is useful for businesses that are interested in Power Platform expansions.
- The dual-write infrastructure follows the no-code/low-code principle. Minimal engineering effort is required to extend the standard table-to-table maps and to include custom maps.
- Dual-write supports both online mode and offline mode. Microsoft is the only company that offers support for online and offline modes.

What does dual-write mean for developers and architects of customer engagement apps?

Dual-write automates the data flow between Finance and Operations apps and customer engagement apps. Dual-write consists of two AppSource solutions that are installed on Dataverse. The solutions expand the table schema, plugins, and workflows on Dataverse so that they can scale to ERP size. For a successful implementation, developers and architects of customer engagement apps must understand these changes and collaborate with their counterparts on Finance and Operations apps.

To create parity with Finance and Operations applications, dual-write makes some crucial changes in the Dataverse schema. If you understand the plan, you can avoid some design and development rework in the future.

- When the dual-write AppSource package is installed, Dataverse will have new concepts such as company and party. These concepts help applications built on Dataverse, including Dynamics 365 Sales, Dynamics 365 Marketing, Dynamics 365 Customer Service, and Dynamics 365 Field Service, to interact seamlessly with Finance and Operations apps.
- Activities and notes are unified and expanded to support both C1s (users of the system) and C2s (customers of the system).
- To prevent data loss during currency transmission between Finance and Operations apps and the
Dataverse, you’ll be able to extend the number of decimal places in the currency data type of customers engagement apps. The feature autotranslates existing rows to the new extended state at the metadata layer. During this process, the currency value is translated to decimal data rather than money data, and the currency value supports 10 decimal places. This feature is opt-in, and organizations that don’t need more than 4 decimal places of precision do not need to opt in. For more information, see Currency data-type migration for dual-write.

- **Date effectivity** will be added to Dataverse. It will support past, present, and future data on the same table.
- **Product unit conversions** are supported for products, quotes, orders, and invoices.

For more information about upcoming changes, see What’s new or changed in dual-write.
The setup of a dual-write connection has the following requirements:

- Finance and Operations apps that have build version 10.0.9 (10.0.383.20013) (Quality update) and platform update 33 or later
- Customer engagement apps that have platform version 9.1.0000.11732 or later

Dual-write has these limitations:

- You can't run dual-write and the Prospect to cash solution for Data integrator side by side. If you're running the Prospect to cash solution for Data integrator, you must uninstall it.
- Dual-write setup is not supported on trial instances of Finance and Operations apps.
- Dual-write must be used to integrate a single Finance and Operations app instance and a single customer engagement app instance.
- Dual-write currently has an initial synchronization limit of 40 legal entities.
- Dual-write live synchronization has a limit of 250 legal entities.
- Dual-write does not support cross-company data sharing.
- Dual-write requires that the Finance and Operations app and the customer engagement app must be in the same Microsoft Azure Active Directory (Azure AD) tenant.
- Dual-write requires that the Finance and Operations app and the customer engagement app must be deployed in the same Microsoft Azure datacenter.
- Dual-write is not triggered by the doInsert, doUpdate, and doDelete events of Finance and Operations apps. Use the Insert, Update, and Delete events in Finance and Operations apps when you want to trigger dual-write.
- Dual-write doesn't support distributed transactions. For example, if the product receipt posting process is cancelled, dual-write might create the product receipt in Dataverse but not create it in Supply Chain Management.

One Version

Future updates of the dual-write solution will be available through One Version.
You can set up a dual-write connection between a Finance and Operations environment and a Dataverse environment.

- A **Finance and Operations environment** provides the underlying platform for **Finance and Operations apps** (for example, Microsoft Dynamics 365 Finance, Dynamics 365 Supply Chain Management, Dynamics 365 Commerce, and Dynamics 365 Human Resources).
- A **Dataverse environment** provides the underlying platform for **customer engagement apps** (Dynamics 365 Sales, Dynamics 365 Customer Service, Dynamics 365 column Service, Dynamics 365 Marketing, and Dynamics 365 Project Service Automation).

The setup mechanism varies, depending on your subscription and the environment:

- For new instances of Finance and Operations apps, the setup of a dual-write connection begins in Microsoft Dynamics Lifecycle Services (LCS). If you have a license for Microsoft Power Platform, you will get a new Dataverse environment if your tenant doesn’t have one.
- For existing instances Finance and Operations apps, the setup of a dual-write connection begins in the Finance and Operations environment.

Before you start dual-write on an entity, you can run an initial synchronization to handle existing data on both sides: Finance and Operations apps and customer engagement apps. You can skip the initial synchronization if you don’t have to sync data between the two environments.

An initial synchronization lets you copy existing data from one app to another bidirectionally. There are several setup scenarios, depending on the environments that you already have and the type of data in them.

The following setup scenarios are supported:

- A new Finance and Operations app instance and a new customer engagement app instance
- A new Finance and Operations app instance and an existing customer engagement app instance
- A new Finance and Operations app instance that has data and a new customer engagement app instance
- A new Finance and Operations app instance that has data and an existing customer engagement app instance
- An existing Finance and Operations app instance and a new customer engagement app instance
- An existing Finance and Operations app instance and an existing customer engagement app instance

A new Finance and Operations app instance and a new customer engagement app instance
To set up a dual-write connection between a new instance of a Finance and Operations app that has no data and a new instance of a customer engagement app, follow the steps in Dual-write setup from Lifecycle Services. When the connection setup is completed, the following actions automatically occur:

- A new, empty Finance and Operations environment is provisioned.
- A new, empty instance of a customer engagement app is provisioned, where the CRM prime solution is installed.
- A dual-write connection is established for DAT company data.
- Table maps are enabled for live synchronization.

Both environments are then ready for live data synchronization.

A new Finance and Operations app instance and an existing customer engagement app instance

To set up a dual-write connection between a new instance of a Finance and Operations app that has no data and an existing instance of a customer engagement app, follow the steps in Dual-write setup from Lifecycle Services. When the connection setup is completed, the following actions automatically occur:

- A new, empty Finance and Operations environment is provisioned.
- A dual-write connection is established for DAT company data.
- Table maps are enabled for live synchronization.

Both environments are then ready for live data synchronization.

To sync the existing Dataverse data to the Finance and Operations app, follow these steps.

1. Create a new company in the Finance and Operations app.
2. Add the company to the dual-write connection setup.
4. Run the Initial sync functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the Example section later in this topic.

A new Finance and Operations app instance that has data and a new customer engagement app instance

To set up a dual-write connection between a new instance of a Finance and Operations app that has data and a new instance of a customer engagement app, follow the steps in the A new Finance and Operations app instance and a new customer engagement app instance section earlier in this topic. When the connection setup is completed, if you want to sync the data to the customer engagement app, follow these steps.

1. Open the Finance and Operations app from the LCS page, sign in, and then go to Data Management > Dual-write.
2. Run the Initial sync functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the Example section.
To set up a dual-write connection between a new instance of a Finance and Operations app that has data and an existing instance of a customer engagement app, follow the steps in the **A new Finance and Operations app instance and an existing customer engagement app instance** section earlier in this topic. When the connection setup is completed, if you want to sync the data to the customer engagement app, follow these steps.

1. Open the Finance and Operations app from the LCS page, sign in, and then go to **Data Management > Dual-write**.
2. Run the **Initial sync** functionality for the tables that you want to sync data for.

To sync the existing Dataverse data to the Finance and Operations app, follow these steps.

1. Create a new company in the Finance and Operations app.
2. Add the company to the dual-write connection setup.
3. **Bootstrap** the Dataverse data by using a three-letter ISO company code.
4. Run the **Initial sync** functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the **Example** section.

**An existing Finance and Operations app instance and a new customer engagement app instance**

The setup of a dual-write connection between an existing instance of a Finance and Operations app and a new instance of a customer engagement app occurs in the Finance and Operation environment.

1. **Set up the connection from the Finance and Operations app.**
2. Run the **Initial sync** functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the **Example** section.

**An existing Finance and Operations app instance and an existing customer engagement app instance**

The setup of a dual-write connection between an existing instance of a Finance and Operations app and an existing instance of a customer engagement app occurs in the Finance and Operation environment.

1. **Set up the connection from the Finance and Operations app.**
2. To sync the existing Dataverse data to the Finance and Operations app, **bootstrapping** the Dataverse data by using a three-letter ISO company code.
3. Run the **Initial sync** functionality for the tables that you want to sync data for.

For links to an example and an alternative approach, see the **Example** section.

**Example**

For an example, see **Enabling the Customers V3—Contacts table map**

For an alternative approach that is based on data volumes in each entity that must run an initial synchronization, see **Considerations for initial synchronization**.
Before you start dual-write on a table, you can run an initial synchronization to handle existing data on both sides: Finance and Operations apps and customer engagement apps. You can skip the initial synchronization if you don’t have to sync data between the two environments.

The initial synchronization lets you copy existing data from one app to another bidirectionally, and there are several considerations when you run it. For example, you might have to migrate data before your go-live. In this case, data can be loaded into one side through data migration and then synced to the other side through the initial synchronization.

We recommend that you use the following approach for the initial synchronization:

- **Single-threaded tables**: First migrate data into the Finance and Operations app, and then trigger the initial synchronization to move the data over to Dataverse. Based on lab testing that Microsoft has done, this sequence has better performance than synchronization from Dataverse to Finance and Operations apps.
- **Multi-threaded tables**: First migrate data into Dataverse, and then trigger the initial synchronization to move the data over to the Finance and Operations app.

**Constraints**

**Data migration slow-down with enabled dual-write**

If you first activate the map in dual-write and then start to import data, migration performance will be poor. We recommend that you not activate running maps in dual-write until the data migration is completed.

**Limit of 500,000 rows per run**

The maximum number of rows that is allowed through initial synchronization is 500,000 per run. The limit of 500,000 rows applies to each legal table, because each legal entity runs separately. For more information, see [*Integrate data into Dataverse*](#). In particular, pay attention to the note that states, “To optimize performance and not overload the apps, we currently limit project executions to 500k rows per execution per project.”

If there must be more than 500,000 rows in a run when you the initial synchronization, we recommend that you migrate data into the Finance and Operations app and Dataverse separately, and skip the initial synchronization.

**Twenty-four-hour limit**

If you're running the initial synchronization from Dataverse to the Finance and Operations app, the import result must be received back from the Finance and Operations app within 24 hours. Otherwise, a time-out occurs. Therefore, if you're syncing lots of data, and the single run takes more than 24 hours, the initial synchronization might fail because of a time-out. For example, an initial synchronization from Dataverse to a Finance and Operations app for the **Customer/Account** table involves 70,000 rows. Therefore, the run might take more than 24 hours and time out.

Don’t run the initial synchronization from Dataverse to a Finance and Operations app for **single-threaded tables** if the data volume is more than 70,000 rows. Because these tables don’t support multi-threading during import, a time-out might occur if the volume is more 70,000 rows. In this situation, you should migrate data into the Finance and Operations app and Dataverse separately, and skip the initial synchronization.

**Limit of 40 legal entities while the environments are being linked**

Currently, there is a limit of 40 legal entities while the environments are being linked. If you try to enable maps where more than 40 legal entities are linked between the environments, you will receive the following error.
Initial synchronization isn't currently supported for table maps that have 10 or more lookups

This limitation applies only to the initial synchronization from Dataverse for table maps that have 10 or more lookups. If you run the initial synchronization against a table map that has 10 or more lookups, you might receive the following error message:

5 Attempts to get data from https://XXXX.azure-apim.net/apim... Failed

As a workaround you can split the initial sync into these steps:

1. Remove some of the lookup columns that are not mandatory from the dual-write table map and bring the number of lookups to 10.
2. After the lookup columns are removed, save the map and do the initial sync.
3. After the initial sync for the first step is successful, add the remaining lookup columns and remove the lookup columns that were synced in first step. Once again make sure the number of lookup columns is 10. Save the map and run the initial sync. Repeat these steps to make sure all the lookup columns are synced.
4. Add all the lookup columns back to the map, save the map and run the map with skip initial sync. This will enable the map for live sync mode.

Five-minute limit for Finance and Operations data export

If you're running the initial synchronization from the Finance and Operations app to Dataverse and the Finance and Operations data export takes more than five minutes, then the initial sync might time out. The time-out can happen if the data table has virtual columns with the `postLoad` method, or the export query isn't optimized (for example, if it has missing indexes).

This type of synchronization is supported in Platform update 37 (PU37) and later. Therefore, you should update your Finance and Operations app to PU37 or later.

Security role for write access

Every user in a customer engagement organization with dual-write must be added to the Dual-Write Runtime User role. Without this role, users will be unable to create any rows in tables in the customer engagement organization.

Company and Currency Exchange Tables Required Security Role

Company and currency exchange tables are global in nature and all dual-write users require read access to these 2 tables. To provide access, all dual-write users will need to be added to the Dual-Write App User security role. If a user does not have this security role assigned to them, they will be unable to read tables that contain Company and Currency values.

Error handling capabilities

Initial synchronization is always a full push

If an individual row fails to be synced, you can't resync only that individual row. The initial synchronization always pushes the whole data set. This behavior is known as a full push. If the initial synchronization only partially succeeds, a second synchronization runs for all the rows, not just the rows that failed to be synced during the initial synchronization.

Only the top five errors can be viewed

You can view only the top five errors from the initial synchronization error log.
Known issues

For information about known issues, see Troubleshoot issues during initial synchronization.

> 500,000 Any

1. Bootstrap Dataverse for the company code.
2. Migrate data to each app outside the initial synchronization.
3. Activate dual-write, and skip the initial synchronization.

**Single-threaded tables**

- Sales tax codes (msdyn_taxcodes)
- Customers V3 (accounts)
- Vendors V2 (msdyn_vendors)
- Warehouses (msdyn_warehouses)
- Product categories (msdyn_productcategories)
- Employment (cdm_employments)
- Position worker assignments (cdm_positionworkerassignmentmaps)
- Warehouse locations (msdyn_inventorylocations)
- Modes of delivery (msdyn_shipvias)
For more consistent availability and performance, limits apply when dual-write is used to write data to Finance and Operations apps and Microsoft Dataverse. These limits control dual-write transactions and are applied at the platform level. They are designed to ensure seamless writes and to help minimize failures.

Finance and Operations apps and Dataverse have many processes that span large numbers of records and complex, multi-table transactions. Each environment has limits on the number of transactions, the number of records per transaction, and transaction time (that is, the time that is required to process the transaction). It’s important that you understand these limits and their effect on the live synchronization capabilities of dual-write.

**Legal Entities**

Live synchronization supports up to 250 legal entities per transaction. This is different from initial synchronization which supports only 40 due to larger data volumes and related operations.

**Transaction patterns**

A process can write data in two different transaction patterns:

- **Single transaction** – All data that is written as part of the process is part of a single transaction.
- **Multiple transactions** – All the data that is written as part of the process is split into multiple transactions.

**Single transaction**

In a single transaction, all data that is written as part of the process is part of a single transaction. If a failure occurs, the whole transaction is rolled back.

A common example is a process that creates multiple invoices in a single transaction. In this case, either all invoices are committed in one transaction or, if an error occurs, all invoices are rolled back. The following code examples create multiple invoices in a single transaction.

```plaintext
// Transaction start
Invoice1.create();
Invoice2.create();
Invoice3.create();
// Additional invoices.
InvoiceN.create();
ttscommit;// Transaction end
```

**Multiple transactions**

In multiple transactions, all the data that is written as part of the process is split into multiple transactions. If a failure occurs, the whole group of multiple transactions isn’t rolled back. Instead, each transaction is independently rolled back or committed. Any transaction that has a failure is rolled back. Any transaction that
has no failure is committed.

A common example is a process that creates multiple invoices. Each invoice is created in a separate transaction, and if an error occurs, only the invoice that is included in a specific transaction is rolled back. The remaining invoices are successfully committed. The following code examples create multiple invoices, one per transaction.

```csharp
  ttsbegin; // Transaction start
  Invoice1.create();
  ttscommit;// Transaction end

  ttsbegin;// Transaction start
  Invoice2.create();
  ttscommit;// Transaction end

  ttsbegin;// Transaction start
  Invoice3.create();
  ttscommit;// Transaction end

  // Additional transactions.

  ttsbegin;// Transaction start
  InvoiceN.create();
  ttscommit;// Transaction end
```

### Transaction time limit

When dual-write is used to write records to Finance and Operations apps or Dataverse, each transaction must be completed within a specific amount of time. If a transaction isn't completed before the transaction time limit is reached, the records aren't committed to Finance and Operations apps and Dataverse by using dual-write. In this case, the records in the transaction are rolled back in both the Finance and Operations environment and the Dataverse environment.

For example, when dual-write is used to sync contract renewals from Finance and Operations apps to Dataverse, the timer begins when the business logic in Finance and Operations apps is completed and the Dataverse process is started. The timer ends when the transaction is committed. The whole time that is spent in Dataverse includes the time that is required to write, and also the time that is required to process the standard and custom plugins. If the transaction exceeds the time limit, the records aren't committed to Dataverse.

The same principle applies when dual-write is used to write data in the other direction, from Dataverse to Finance and Operations apps.

### Dual-write live synchronization limits

The following tables describe the dual-write live synchronization limits that apply when data is written between Finance and Operations apps and Dataverse. These limits are specific to the direction of the data flow: from Finance and Operations apps to Dataverse, or from Dataverse to Finance and Operations apps.

#### From Finance and Operations apps to Dataverse

The following limits apply when data is written from Finance and Operations apps to Dataverse.
### MEASURE | LIMITS
--- | ---
Number of transactions | The total number of transactions that you can perform per day per tenant is governed by service protection API limits that are designed to detect when client applications make extraordinary demands on server resources. For more information, see Service protection API limits.

Number of records per single transaction | 1,000 records
If there are more than 1,000 records in a single transaction, consider splitting that transaction into multiple transactions. For more information, see the Transactions with more than 1,000 records section of this topic.

Transaction time limit | 2 minutes

### From Dataverse to Finance and Operations apps

The following limits apply when data is written from Dataverse to Finance and Operations apps.

### MEASURE | LIMITS
--- | ---
Number of transactions | The number of transactions might be affected by priority-based throttling limits that are designed to help prevent over-utilization of resources and preserve system responsiveness. For more information, see Priority-based throttling.

Number of records per single transaction | A payload size limit on Dataverse limits the number of records that can be transferred. The limit is 116.85 megabytes (MB) per transaction. For more information, see Error: Message size exceeded when sending context to Sandbox. Use of this limit depends on the multiple factors, such entity complexity, the type of columns that is used, and mapped fields. Therefore, the limit can't be expressed as a simple number of records.

If the limit is exceeded, Dataverse rejects the transaction (referred to as a message), and the following error code is used:

*Error Code: -2147220970 Error Message: Message size exceeded when sending context to Sandbox. Message size: ### MB*

If the size of the records in a single transaction exceeds 116.65 MB, consider splitting the transaction into multiple transactions. For more information, see the Transactions with more than 1,000 records section of this topic.

Transaction timeout | 2 minutes

### Transactions with more than 1,000 records

Scenarios where transactions have more than 1,000 records are common. In these scenarios, we recommend that you split single transactions into multiple transactions. The following code examples show how to make multiple transactions, based on record IDs.
ttsbegin; // Transaction start.
   Invoice1.create();
   Invoice2.create();
   // Additional invoices.
   Invoice1000.create();
ttscommit; // Transaction end.

   ttsbegin; // Transaction start.
   Invoice1001.create();
   Invoice1002.create();
   // Additional invoices.
   Invoice2000.create();
ttscommit; // Transaction end.

   ttsbegin; // Transaction start.
   Invoice2001.create();
   Invoice2002.create();
   // Additional invoices.
   Invoice3000.create();
ttscommit; // Transaction end.

   // Additional transactions.
   ttsbegin; // Transaction start.
   Invoice(N)1.create();
   Invoice(N)2.create();
   // Additional invoices.
   Invoice(N+1)000.create();
ttscommit; // Transaction end.

   i = 1;
   committPending = false;
   while /* loop condition */
   {
      if (i==1)
      {
         ttsbegin; // Transaction start.
            committPending = true;
      }
   InvoiceN.create();
   if (i == 1000)
      {
         ttscommit; // Transaction end.
            committPending = false;
            i = 0;
      }
      i++;
   }

   if (committPending == true)
   {
      ttscommit; // Transaction end.
   }
This topic explains how to enable dual-write from Microsoft Dynamics Lifecycle Services (LCS).

Prerequisites

You must complete the Power Platform integration as described in the following topics:

- Power Platform Integration - Enable during environment deployment
- Power Platform integration - Enable after environment deployment

Set up dual-write for new Dataverse environments

Follow these steps to set up dual-write from LCS Environment Details page:

1. On the Environment Details page, expand the Power Platform Integration section.
2. Select the Dual-write application button.
3. Review the terms and conditions, and then select Configure.
4. Select OK to continue.
5. You can monitor the progress by periodically refreshing the environment details page. Setup typically takes 30 minutes or less.
6. When the setup is complete, a message will inform you if the process was successful or if there was a failure. If the setup failed, then a related error message is displayed. You must fix any errors before moving to the next step.
7. Select Link to Power Platform environment to create a link between Dataverse and the current environment's databases. This typically takes less than 5 minutes.
Set up dual-write for an existing Dataverse environment

To set up dual-write for an existing Dataverse environment, you must create a Microsoft support ticket. The ticket must include:

- Your Finance and Operations environment ID.
- Your environment name from Lifecycle Services.
- The Dataverse organization ID or Power Platform Environment ID from Power Platform Admin Center. In your ticket, request that the ID be the instance used for Power Platform integration.

NOTE

You can't unlink environments by using LCS. To unlink an environment, open the Data integration workspace in the Finance and Operations environment, and then select Unlink.

Linking mismatch

It is possible that your LCS environment is linked to one Dataverse instance, while your dual-write environment is linked to another Dataverse instance. This linking mismatch can cause unexpected behavior, and it could end up sending data to the wrong environment. The recommended environment to use for dual-write is the one that is created as part of Power Platform integration, and long term, this will be the only way to establish a link between environments.

If your environment has a linking mismatch, LCS displays a warning on your environment details page similar to "Microsoft has detected that your environment is linked via Dual-write to a different destination than specified in Power Platform Integration, which is not recommended":

If you encounter this error there are two options, based on your needs:
- Unlink and relink dual-write environments (Reset or change linking) as specified on your LCS environment details page. This is the ideal option, because you can run it without Microsoft support.
- If you want to keep your link in dual-write, you can ask for help from Microsoft Support to change the Power Platform integration to use your existing Dataverse environment as documented in the previous section.
Enable dual-write for existing Finance and Operations apps

This set of topics provides step-by-step instructions that explain how to enable dual-write for existing instances of Finance and Operations apps (Microsoft Dynamics 365 Finance and Dynamics 365 Supply Chain Management), and also for a new or existing Dataverse environment.

Step-by-step instructions to enable dual-write for existing instances of Finance and Operations apps and a new or existing Dataverse environment

The process of enabling dual-write has three parts:

1. Make sure that you meet all the system requirements and complete all the prerequisites.
2. Link your Finance and Operations app environment to Dataverse by using the dual-write wizard.
3. Enable the table maps.

Each part is described in a separate topic.

System requirements and prerequisites
What regions are available?

Currently, we support dual-write in the following regions:

- Asia
- Australia
- Canada
- Europe
- India
- Japan
- South America
- United Arab Emirates
- United Kingdom
- United States

Verify requirements and grant access

Before you enable dual-write, follow these steps to make sure that you meet the minimum system requirements and to grant access to the apps that must connect to each other. The dual-write health check validates the prerequisites as you complete the dual-write wizard to link a Finance and Operations app environment to a Dataverse environment.

You must set **Enable Dynamics 365 apps** to **Yes** when you set up the environment, as shown in the following image. Alternatively, you can choose a customer engagement app environment that comes with Dataverse and already has **Enable Dynamics 365 apps** set to **Yes**.
1. Validate the platform update and app version.

   Make sure that your Finance and Operations app environment is running Platform update 33 (app version 10.0.9) or later.

   Related health check result:

   App version is up to date
2. Install the dual-write core solution.

The dual-write core solution contains metadata for your table maps and must be installed in your environments.

a. In Power Apps, in the left pane, select **Solutions**.
b. Select **Open AppSource**.
c. Select the **Dual Write Core** solution.
d. Follow the prompts to import the solution.

Related health check result:

*The dual-write core solution was found*

The dual-write core solution contains metadata for your table maps and must be installed in the environment

3. Grant Dataverse access so that it can connect to a Finance and Operations app.

a. Open your instance of the Finance and Operations app, search and navigate to Azure Active Directory applications.
b. Select **New** to add a new client ID row: `6f7d0213-62b1-43a8-b7f4-ff2bb8b7b452`. This row is the application ID for an app that will be used to connect from Dataverse to the Finance and Operations app.
c. Repeat the previous two steps to add another client ID row: `2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b`.

When you've finished, follow these steps to refresh the list of tables:

a. Go to **Workspaces > Data management**, select the **Data entities** tile, and make sure that the entity list is filled in.
b. Go to **Workspaces > Data management**, and select the **Framework parameters** tile. Then, on the **Entity settings** tab (https://<BaseFinanceandOperationsappsURL?>/?cmp=USMF&mi=DM_DataManagementWorkspaceMenu&TableName=DMFDefinitionGroupEntity), select **Refresh entity list**.

Related health check result:
The Dataverse can connect to the Finance and Operations app

Before you can enable dual-write, you must grant access to the apps to connect to each other

App user with id 6f7d0213-62b1-43a8-b7f4-ff2bb8b7b452 exists
App user with id 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b exists

4. Grant a Finance and Operations app access so that it can connect to Dataverse. Follow the steps in Create an application user, using the following information for applications IDs and security roles.

- **Applications**: Add users to these applications:
  - 00000015-0000-0000-c000-000000000000
  - 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b

- **Security roles**: Select a preconfigured Security Role to grant a Read privilege with a User scope for each table integrated through dual-write.

  **NOTE**
  Company and currency exchange tables are global in nature and all dual-write users require read access to these 2 tables. All dual-write users will need to be added to the Dual-Write App User security role. In order to allow non-administrator users to create rows in a dual-write enabled table, they will need to be assigned the Dual-Write Runtime User security role.

For instructions on how to create a Security Role, see Create or configure a custom security role.

  **NOTE**
  The root business unit’s default team will become the default owner for all rows integrated through dual-write. Because that team must be assigned a security role, this means that all users in the root business unit will inherit the security role. This means that at the very least, users from that business unit will have read access to all the rows that are owned by that team. If this isn’t the desired behavior, make sure that users are not a member of the root business unit.

**Related health check result:**

The Finance and Operations app can connect to the Dataverse

Before you can enable dual-write, you must grant access to the apps to connect to each other

App user with id 00000015-0000-0000-c000-000000000000 exists
App user with id 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b exists

5. Provide app consent in the tenant. For dual-write core solution version 1.0.16.0 or above, this step is no longer needed.

**Related health check result:**

Apps in tenant

The required dual-write applications need to be installed in the tenant.

App ID: 6f7d0213-62b1-43a8-b7f4-ff2bb8b7b452
App ID: 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b

6. Make sure that the dual-write plug-ins are enabled.

This step isn’t usually required, because the plug-ins should be enabled as part of the process of installing the dual-write core solution. However, if the health check fails, follow these steps to manually enable the dual-write plug-ins:

a. Download the Plug-in Registration Tool.

In the Plugin Registration Tool, there should be two plug-in assemblies that are associated with
dual-write: DualWriteRegistration.Plugins and DualWriteRuntime.Plugins. These assemblies have plug-in steps that must be enabled, in order, before dual-write can be used. To view the plug-in steps, expand a plug-in assembly and its plug-in types. All the steps that belong to the dual-write plug-in assemblies should be enabled.

b. To enable a step, select and hold the step (or right-click it), and then select Enable. If no Enable option is available, only a Disable option, the step has already been enabled and doesn't have to be changed.

If the dual-write plug-in assemblies can't be found, import the latest version of the dual-write core solution.

Related health check result:
The dual-write registration and runtime plugins are enabled
To ensure listening into CRUD operations on the Dataverse, the dual-write plugins need to be enabled

7. Install the Dual-write application orchestration solution maps solution.

In Power Apps, in the left pane, select Solutions. Select Open AppSource, and search for the solution that is named Dual-write application orchestration solution. Select the solution, and follow the prompts to import it. After installation, you'll find several new solutions listed under Solutions. For more information, see Solutions overview.

While the dual-write core solution contains metadata for your table maps, the dual-write application orchestration solution covers these additional master data scenarios:

- Customers, products, and vendors.
- End-to-end process flows like prospect to cash.
- On-demand functions like pricing.
- Reference data for ledger, tax, payment terms, and schedules.

Dual-write will continue to expand in the future to support more scenarios including party, project, and hands-on inventory. The framework is extensible and accommodates customer-centric business data exchange through a few additional clicks.
8. Uninstall the Prospect to Cash (P2C) solution.

The P2C solution doesn't work concurrently with dual-write. Therefore, don't install the P2C solution. If it's already installed, you must uninstall it before you enable dual-write.

9. Provide the supported tenant configuration.

Make sure that the Finance and Operations app and Dataverse are installed under the same tenant. Cross-tenant scenarios aren't currently supported.

For dual-write core solution lower than version 1.0.16.0 only

1. In step Step 3b above, create a new client ID row: 33976c19-1db5-4c02-810e-c243db79efde (versus 6f7d0213-62b1-43a8-b7f4-ff2bb8b7b452).

2. Add app consent in the tenant:

   a. Open the following URL, and sign in by using your admin credentials. You should be prompted for consent.

      https://login.microsoftonline.com/common/oauth2/authorize?client_id=33976c19-1db5-4c02-810e-c243db79efde&response_type=code&prompt=admin_consent

   b. Select Accept.

      By selecting Accept, you indicate that you're providing consent to install the app that has application ID 33976c19-1db5-4c02-810e-c243db79efde in your tenant. Dataverse requires this app to communicate with the Finance and Operations app.

Related health check result:

Apps in tenant

The required dual-write applications need to be installed in the tenant.

   App ID: 33976c19-1db5-4c02-810e-c243db79efde
   App ID: 2e49aa60-1bd3-43b6-8ab6-03ada3d9f08b

Next steps

Use the dual-write wizard to link your environments
1. Sign in to the Finance and Operations app environment that you want to link to your Dataverse environment.

2. Go to **Workspaces > Data management**, and select the **Dual Write** tile.

3. Select **New link to environment** to open the **Setup link to Dataverse** wizard.

4. The **Choose environment** page lists all the Dataverse environments where the signed-in user is an environment admin. Select the Dataverse environment to link to, and then select **Next**.
5. Select your legal entities, and then select **Next**.

A health check is run to verify that your system meets the requirements for enabling dual-write. The health check also verifies that all the prerequisites have been completed. If any health check test fails, make sure you've completed all the prerequisites before you move on to the next step.

In the following example, the test about whether access was granted to connect the apps failed. In this case, you must first grant access to connect the apps by creating the appropriate application IDs. You must then rerun the wizard.

6. Review the summary, privacy notice, and consent, and then select **Create**.

You’ve now linked your Finance and Operations app to the Dataverse environment.

**NOTE**

If you don’t see your table maps, or if you see a blank page, be sure to **Apply** the Dual-write application orchestration solution that you installed as part of the system requirements and prerequisites.

7. Apply the dual-write application orchestration solution.
In the Finance and Operations app, on the **Dual-write** page, select **Apply Solution** to apply the table maps that you just downloaded and installed. After you apply the solution, you should see that the default table maps are published.

You've now successfully imported and applied a Microsoft-published dual-write table map solution to your environment.

**Next steps**

**Enable table maps for dual-write**
When you enable a table map for dual-write, it begins at the **Not running** status. The table map then goes through an initialization phase, where it does an initial write by copying pre-existing data on tables on both sides. Finally, when the table is completely enabled, the table map sets the status to **Running**.

During the initialization phase, any pre-existing data that you have is copied as part of the initial write phase.

<table>
<thead>
<tr>
<th>STATUS</th>
<th>DESCRIPTION</th>
<th>AVAILABLE ACTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not running</td>
<td>The table has not yet been enabled for dual-write. Every table begins at the <strong>Not running</strong> status.</td>
<td>Run</td>
</tr>
<tr>
<td>Initializing</td>
<td>The initial write is occurring.</td>
<td>None</td>
</tr>
<tr>
<td>Running</td>
<td>The table has been enabled for dual-write.</td>
<td>Stop, Pause</td>
</tr>
<tr>
<td>Paused</td>
<td>The table is in a paused state, and all new requests are queued.</td>
<td>Run</td>
</tr>
<tr>
<td>Resuming</td>
<td>The table is catching up on rows that were queued while the table was paused.</td>
<td>None</td>
</tr>
</tbody>
</table>

While the status is **Running**, you can pause a table. All changes are then queued until you resume. When you resume, the table goes into "catch-up mode," where all the queued changes are played back.

The following illustration shows an example of a table that is paused.
Entities have several dependent tables. For example, Customer-Contact tables have customer groups and currencies as dependent tables.

Because these are relational apps that have relational data, if you don’t enable the dependent tables, you might encounter errors later. To help prevent these errors, before you enable a table map, you’re provided with a list of the related tables that we recommend that you enable.

Example: Enabling the Customers V3—Contacts table map

When you select a table map (for example, Customers V3—Contacts) and select Run, a dialog box appears before the table map is enabled. This dialog box lists all the dependent tables. You can select the Show related table map(s) option to show all the related table maps. To enable the selected table map and all its related tables, select Run in the dialog box.

NOTE
The behavior is similar when you pause a table. In that case, you have the option to pause all the related tables too.
Criteria for linking tables

To enable table maps for dual-write, you must define an alternative key in Dataverse. The value of the alternative key in Dataverse must match the key that is defined in the Finance and Operations app.

For example, in a Finance and Operations app, CustomerAccount is the key for the Account table.
In Dataverse, `accountnumber` is defined as the key for the Account table.

In the Customers V3 table map, you can see that `accountnumber` is mapped to `CustomerAccount`.
Next steps

Customize table and column mappings
You can increase the number of decimal places that are supported for currency values to a maximum of 10. The default limit is four decimal places. By increasing the number of decimal places, you help prevent data loss when you use dual-write to sync data. The increase in the number of decimal places is an opt-in change. To implement it, you must request assistance from Microsoft.

The process of changing the number of decimal places has two steps:

1. Request migration from Microsoft.
2. Change the number of decimal places in Dataverse.

The Finance and Operations app and Dataverse must support the same number of decimal places in currency values. Otherwise, data loss can occur when this information is synced between apps. The migration process reconfigures the way that currency and exchange rate values are stored, but it doesn't change any data. After the migration is completed, the number of decimal places for currency codes and pricing can be increased, and the data that users enter and view can have more decimal precision.

Migration is optional. If you might benefit from support for more decimal places, we recommend that you consider migration. Organizations that don't require values that have more than four decimal places don't have to migrate.

**Requesting migration from Microsoft**

Storage for existing currency columns in Dataverse can't support more than four decimal places. Therefore, during the migration process, currency values are copied to new internal columns in the database. This process occurs continuously until all data has been migrated. Internally, at the end of migration, the new storage types replace the old storage types, but the data values are unchanged. The currency columns can then support up to 10 decimal places. During the migration process, Dataverse can continue to be used without interruption.

At the same time, exchange rates are modified so that they support up to 12 decimal places instead of the current limit of 10. This change is required so that the number of decimal places is the same in both the Finance and Operations app and Dataverse.

Migration doesn't change any data. After the currency and exchange rate columns are converted, admins can configure the system to use up to 10 decimal places for currency columns by specifying the number of decimal places for each transaction currency and for pricing.

**Request a migration**

To make this feature available, email **CDSExpandDecimal@microsoft.com**, and include the following information:

- **Subject**: Request to enable expanded decimal support for <organizationID>
- **Body**: I would like to enable expanded decimal support for my org <organizationID>.

A Microsoft representative will contact you within two to three business days for the next steps.

When you request a migration, you should be aware of the following details and plan for them accordingly:

- The time that is required to migrate the data depends the amount of data in the system. Migration of large databases can take several days.
- The size of the database temporarily increases while the migration is running, because additional space is
needed for indexes. Most of the additional space is freed when the migration is completed.

- During the migration process, if errors occur that prevent the migration from being completed, the system raise alerts to Microsoft Support, so that Support staff can intervene. However, even if errors occur during the migration, Dataverse remains fully available for regular use.
- The migration process isn’t reversible.

**Changing the number of decimal places**

After the migration is completed, Dataverse can store numbers that have more decimal places. Admins can choose how many decimal places are used for specific currency codes and for pricing. Users of Microsoft Power Apps, Power BI, and Power Automate can then view and use numbers that have more decimal places.

To make this change, you must update the following settings in Power Apps:

- **System Settings: Currency precision for pricing** – The Set the currency precision that is used for pricing throughout the system column defines how the currency will behave for the organization when Pricing Precision is selected.
- **Business Management: Currencies** – The Currency Precision column lets you specify a custom number of decimal places for a specific currency. There is a fallback to the organization-wide setting.

There are some limitations:

- You can’t configure the currency column on a table.
- You can specify more than four decimal places only at the Pricing and Transaction Currency levels.

**System Settings: Currency precision for pricing**

After migration is completed, admins can set the currency precision. Go to **Settings > Administration**, and select **System Settings**. Then, on the **General** tab, change the value of the **Set the currency precision that is used for pricing throughout the system** column, as shown in the following illustration.

![System Settings](image)

**Business Management: Currencies**

If you require that the currency precision for a specific currency differ from the currency precision that is used for pricing, you can change it. Go to **Settings > Business Management**, select **Currencies**, and select the currency to change. Then set the **Currency Precision** column to the number of decimal places that you want, as shown in the following illustration.
The number of decimal places that can be configured for specific currency columns is limited to four.
The columns that indicate sales order status have different enumeration values in Microsoft Dynamics 365 Supply Chain Management and Dynamics 365 Sales. Additional setup is required to map these columns in dual-write.

**columns in Supply Chain Management**

In Supply Chain Management, two columns reflect the status of the sales order. The columns that you must map are **Status** and **Document Status**.

The **Status** enumeration specifies the overall status of the order. This status is shown on the order header.

The **Status** enumeration has the following values:

- Open Order
- Delivered
- Invoiced
- Cancelled

The **Document Status** enumeration specifies the most recent document that was generated for the order. For example, if the order is confirmed, this document is a sales order confirmation. If a sales order is partially invoiced, and then the remaining line is confirmed, the document status remains **Invoice**, because the invoice is generated later in the process.

The **Document Status** enumeration has the following values:

- Confirmation
- Picking List
- Packing Slip
- Invoice

**columns in Sales**

In Sales, two columns indicate the status of the order. The columns that you must map are **Status** and **Processing Status**.

The **Status** enumeration specifies the overall status of the order. It has the following values:

- Active
- Submitted
- Fulfilled
- Invoiced
- Cancelled

The **Processing Status** enumeration was introduced so that the status can be mapped more accurately with Supply Chain Management.

The following table shows the mapping of **Processing Status** in Supply Chain Management.
<table>
<thead>
<tr>
<th>PROCESSING STATUS</th>
<th>STATUS IN SUPPLY CHAIN MANAGEMENT</th>
<th>DOCUMENT STATUS IN SUPPLY CHAIN MANAGEMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Open Order</td>
<td>None</td>
</tr>
<tr>
<td>Confirmed</td>
<td>Open Order</td>
<td>Confirmation</td>
</tr>
<tr>
<td>Picked</td>
<td>Open Order</td>
<td>Picking List</td>
</tr>
<tr>
<td>Partially Delivered</td>
<td>Open Order</td>
<td>Packing Slip</td>
</tr>
<tr>
<td>Delivered</td>
<td>Delivered</td>
<td>Packing Slip</td>
</tr>
<tr>
<td>Partially Invoiced</td>
<td>Delivered</td>
<td>Invoice</td>
</tr>
<tr>
<td>Invoiced</td>
<td>Invoiced</td>
<td>Invoice</td>
</tr>
<tr>
<td>Cancelled</td>
<td>Cancelled</td>
<td>Not applicable</td>
</tr>
</tbody>
</table>

The following table shows the mapping of Processing Status between Sales and Supply Chain Management.

<table>
<thead>
<tr>
<th>PROCESSING STATUS</th>
<th>STATUS IN SALES</th>
<th>STATUS IN SUPPLY CHAIN MANAGEMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Active</td>
<td>Active</td>
<td>Open Order</td>

<tr>
<td>Cancelled</td>
<td>Cancelled</td>
<td>Cancelled</td>
</tr>
</tbody>
</table>

**Setup**

To set up the mapping for the sales order status columns, you must enable the IsSOPIntegrationEnabled and isIntegrationUser attributes.

To enable the IsSOPIntegrationEnabled attribute, follow these steps.

1. In a browser, go to `https://<test-name>.crm.dynamics.com/api/data/v9.0/organizations`. Replace `<test-name>` with your company’s link to Sales.

2. On the page that is opened, find `organizationid`, and make a note of the value.
3. In Sales, open the browser console, and run following script. Use the `organizationid` value from step 2.

```javascript
Xrm.WebApi.updateRecord("organization",
"d9a7c5f7-acbf-4aa9-86e8-a891c43f748c", {"issopintegrationenabled": true}).then(
    function success(result) {
        console.log("Account updated");
        // perform operations on row update
    },
    function (error) {
        console.log(error.message);
        // handle error conditions
    }
);
```

4. Verify that `IsSOPIntegrationEnabled` is set to `true`. Use the URL from step 1 to check the value.

To enable the `isIntegrationUser` attribute, follow these steps.

1. In Sales, go to `Setting > Customization > Customize the System`, select `User table`, and then open `Form > User`. 
2. In Field Explorer, find **Integration user mode**, and double-click it to add it to the form. Save your change.

3. In Sales, go to **Setting > Security > Users**, and change the view from **Enabled Users** to **Application Users**.
4. Select the two entries for **DualWrite IntegrationUser**.

5. Change the value of the **Integration user mode** column to **Yes**.
Your sales orders are now mapped.
You can filter intercompany orders so that the **Orders** and **OrderLines** tables aren’t synced. In some scenarios, the intercompany order details aren’t required in a customer engagement app.

Each standard Dataverse table is extended through references to the **IntercompanyOrder** column, and the dual-write maps are modified so that they refer to the additional columns in the filters. Therefore, the intercompany orders are no longer synced. This process helps prevent unnecessary data in the customer engagement app.

1. **Extend the CDS Sales Order Headers** table by adding a reference to the **IntercompanyOrder** column. This column is filled in only on intercompany orders. The **IntercompanyOrder** column is available in the **SalesTable** table.

2. **After CDS Sales Order Headers** is extended, the **IntercompanyOrder** column is available in the mapping. Apply a filter that has **INTERCOMPANYORDER = ""** as the query string.

3. **Extend the CDS Sales Order Lines** table by adding a reference to the **InterCompanyInventTransId** column. This column is filled in only on intercompany orders. The **InterCompanyInventTransId** column is available in the **SalesLine** table.

4. **After CDS Sales Order Lines** is extended, the **IntercompanyInventTransId** column is available in the
5. Repeat steps 1 and 2 to extend the Sales Invoice Header V2 table and add a filter query. In this case, use \( \text{INTERCOMPANYORDER} == "\" && \text{SALESORDERNUMBER} != "\" \) as the query string for the filter.

6. Repeat steps 3 and 4 to extend the Sales Invoice Lines V2 table and add a filter query. In this case, use \( \text{INTERCOMPANYINVENTTRANSID} == "\" \) as the query string for the filter.

7. The Quotations table doesn't have an intercompany relationship. If someone creates a quotation for one of your intercompany customers, you can use the CustGroup column to put all those customers into
one customer group. You can extend the header and lines by adding the **CustGroup** column, and then filter so that the group isn’t included.

8. After **Quotations** is extended, apply a filter that has \[\text{CUSTGROUP} \neq \text{"company"}\] as the query string.
The out-of-box table maps have predefined table and column mappings that enable the flow of data between two apps. In this way, they serve as "blueprints." However, because every business is different, the default table maps might sometimes not be enough. Therefore, dual-write fully supports customization by providing ways to change table maps and column mappings.

**Customize column mappings, add transforms, and enable filtering**

1. In your Finance and Operations app, on the Dual-write page, on the Table mappings tab, select the table map to customize.

   **NOTE**
   Before you change table mappings, they must be stopped (not running). Otherwise, your changes won't be saved.

2. On the Table mappings tab, you can customize a column by selecting a new or custom column from either the Finance and Operations app or Dataverse.

   ![Customize Column Mappings](image.png)

3. You can customize the synchronization direction (unidirectional or bidirectional) and add transforms by selecting the map type.
The following table describes the available synchronization directions.

<table>
<thead>
<tr>
<th>SYMBOL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>➡️⬅️</td>
<td>Bidirectional column assignment</td>
</tr>
<tr>
<td>➡️</td>
<td>Bidirectional column assignment that uses transforms</td>
</tr>
<tr>
<td>➢</td>
<td>Unidirectional column assignment (left to right)</td>
</tr>
<tr>
<td>➢</td>
<td>Unidirectional column assignment (right to left)</td>
</tr>
<tr>
<td>➡️</td>
<td>Unidirectional column assignment that uses transforms (left to right)</td>
</tr>
<tr>
<td>⬅️</td>
<td>Unidirectional column assignment that uses transforms (right to left)</td>
</tr>
</tbody>
</table>

The following table describes the available transform types.

<table>
<thead>
<tr>
<th>TRANSFORM TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>Default values are values that are applied to destination columns when no source column value is available. Use default values for columns that are required on the destination table when you have no corresponding source column.</td>
</tr>
<tr>
<td>Value map</td>
<td>Value maps define how values that are present in one table should be mapped to values in the other table.</td>
</tr>
</tbody>
</table>

4. You can add a new column by selecting **Add mapping** and then selecting an existing or custom column in the list.

The following illustration shows an example where a new **birthdate** column is being added.
5. When you’ve finished customizing the column mappings, select **Save**. Then follow the prompts to specify a publisher and a version number.

**Filter your data**

Dual-write lets you filter data by using Open Data Protocol (OData) filter expressions for Dataverse. For the Finance and Operations app, filtering resembles range expressions that are used in the query range.

1. On the table mapping page, select the filter button (funnel symbol).
2. In the **Edit query** dialog box, specify your filters. In this example, the filter that is specified will return only accounts where the account type equals 3.

The following table shows some examples of filter expressions.

<table>
<thead>
<tr>
<th>FILTER</th>
<th>DATVERSE</th>
<th>FINANCE AND OPERATIONS APPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>String field like</td>
<td><code>startswtih(name, 'A')</code></td>
<td><code>(name like 'A*')</code></td>
</tr>
<tr>
<td>String field not like</td>
<td><code>not contains(name, 'A')</code></td>
<td><code>(!((name like 'A')))</code></td>
</tr>
<tr>
<td>Enumeration fields</td>
<td><code>AccountType == '3'</code></td>
<td><code>(AccountType == AccountType::Customer)</code></td>
</tr>
<tr>
<td>Dates</td>
<td><code>TransactionDate le '2021-06-23'</code></td>
<td><code>((TransactionDate &lt;= '2021-06-23'))</code></td>
</tr>
<tr>
<td>Multiple criteria combined</td>
<td><code>numberofemployees gt 1000 and numberofemployees le 2000</code></td>
<td><code>((numberofemployees &gt; 1000) &amp;&amp; (numberofemployees &lt;= 2000))</code></td>
</tr>
</tbody>
</table>

For more examples that show how to use expressions in query ranges, see [Using Expressions in Query Ranges](#).

Currently, we do not support nested lookups in dual-write source filter. Only standard filter operators...
directly against table columns are supported. For more examples, see Standard filter operators.

Add new table maps

Although Microsoft is continuing to add new tables, you can also add standard or custom table maps.

The following example shows how to add a new table map that is named **Address books**.

1. In the Finance and Operations app, on the **Dual-write** page, select **Add table map**.

![Add table map screenshot](image)

**NOTE**

When you create a new solution that uses these modified table maps, you must specify the same publisher:

2. Confirm the table maps that you just modified and added. Be sure to enable and test them, to ensure that they work as you expect.
Next steps

Error management and alert notifications
Dual-write provides out-of-box maps for some business processes. However, there might be scenarios where you need additional fields, maps, or transformations. The dual-write platform is extensible. You can create custom maps and extend existing maps with custom fields to sync data between Finance and Operations apps and Microsoft Dataverse. This topic provides guidance and best practices for these customizations.

Before you customize any maps, you should be familiar with the tasks in Customize table and column mappings.

**Guidance when the entity is in both the Finance and Operations app and Dataverse**

If the entity is in both environments, create a dual-write map.

- Integration keys for the entity should match in both environments. If the entity key isn’t available on either side, be sure to create entity keys. The integration key fields should be mapped to each other in the map.
- The company field should not be present in the mapping if the entity is legal entity-specific, because the company field will already be part of the key. For an example, review the Customer groups (msdyn_customergroups) entity mapping.
- Add filters to either the Finance and Operations environment or the Dataverse environment to trigger the dual-write map only on specific criteria. The Customers V3 - Accounts or CDS Contacts V2 (Contacts) map has several filters that you can use as examples.

**Guidance when the entity is in the Finance and Operations app only**

If the entity is in the Finance and Operations app only, create a new entity in Dataverse, and then add a map.

- If the Finance and Operations entity contains data that is legal entity-specific, be sure to add a lookup field to cdm_companies in the new Dataverse entity. If the Finance and Operations entity is global, a field for the company isn't required in the Dataverse entity.
- Add keys to the Dataverse entity to mimic the Finance and Operations entity key. Dual-write requires the same entity keys in both the Finance and Operations environment and the Dataverse environment. The key fields on the Finance and Operations app and Dataverse should be mapped to each other. Don’t add the company field in the mapping. For an example, review the Vendors V2 - msdyn_vendors mapping.

**Guidance when the entity is in Dataverse only**

If the entity is in Dataverse only, create a new entity in the Finance and Operations environment, and then add a map.

- Create the new entity, and include all the required fields. Make sure that the entity is enabled for Data management and public, so that it can be consumed by OData (Open Data Protocol). For more information about how to create a new entity, see Build and consume data entities.
- If data in the Finance and Operations app should be legal entity-specific, be sure to add a lookup field to cdm_companies in the Dataverse entity. If the Finance and Operations entity is global, a field for the company isn't required in the Dataverse entity.
- Make sure that both entities have the entity key fields. Dual-write requires the same entity keys in both the Finance and Operations environment and the Dataverse environment. The key fields on the Finance and Operations app and Dataverse should be mapped to each other. Don’t add the company field in the
Add attributes to a mapping

If the entities exist in both environments and are mapped, you can add attributes to the map. For more information, see Customize table and column mappings.

Create and update operations don't trigger the synchronization of attributes to Dataverse

In some situations, the entities exist in both environments, but create and update operations don't trigger the synchronization of attributes to Dataverse. Go to the BusinessEventsDefinition table either by using SQL on the Finance and Operations virtual machine (VM) or by using the table browser. Make sure that there is a record for the combination of the affected table that has an updated date (in the RefTableName field) and the entity name (in the RefEntityName field). An example is shown in the following image.

Guidance when entities aren't available in either the Finance and Operations app or Dataverse

If the entities don't exist in either environment, you can create tables in both environments and then create the app by following these steps.

1. In Dataverse, create a new table that has all the required fields. Follow the steps in Create a custom table. If the table should store legal entity–specific data, be sure to add a lookup field to cdm_companies in the new Dataverse table. If the table stores global data, a field for the company isn't required in the Dataverse table.

2. In the Finance and Operations app, create a new entity that has all the required fields. Make sure that the entity is enabled for Data management and public, so that it can be consumed by OData. For more information about how to create a new entity, see Build and consume data entities.

3. To enable table maps for dual-write, define an alternative key in the Dataverse table. The value of the alternative key in Dataverse must match the key that is defined in the Finance and Operations app. For example, in the Finance and Operations app, CustomerAccount is the key for the Account table, as shown in the following illustration.
In Dataverse, `accountnumber` is defined as the key for the `Account` table, as shown in the following illustration.

If you review the `Customers V3` table map, you can see that `accountnumber` is mapped to `CustomerAccount`.
Best practices for dual-write

- Changes must be in a transaction. It's important that you evaluate the number of records per transaction, based on your table design. It's also important that you evaluate how transaction blocks are structured as part of the process in X++. Two examples are shown here.

```plaintext
ttsbegin;
// Transaction start
table1record1.insert();
table1record2.insert();
table1record3.insert();
table1recordN.insert();
ttscommit;
// Transaction end
```

```plaintext
ttsbegin;
// Transaction start
while ( // loop conditions// )
{
  table1recordN.insert();
}
ttscommit;
// Transaction end
```

- The following items aren't handled by business events. Therefore, they aren't handled by dual-write.
  - The `doUpdate` method
  - The `doInsert` method
  - Set-based operations (`insert` and `update`)
  - Records where `skipBusinessEvents(true)` is marked
- Business events must be registered for the data source that is mapped. Data sources aren't tracked if they are outer-joined and marked as read-only in the Finance and Operations app.
- Changes are triggered only if the modifications are on the mapped fields in the Finance and Operations app. In customer engagement apps, all field modifications trigger dual-write synchronization.
Every filter evaluation should provide a valid result.

Data sources aren’t tracked if they don’t have any fields that are mapped.

Entity relationships in the Finance and Operations app must indicate to dual-write that the two entities are linked, and that relationships exist between the two records in the same transaction. Dual-write batching depends on entity relationships that are explicitly defined and considered to sequence the record insertion if both the parent record and child record are part of the same transaction on related entities. If a business process in the Finance and Operations app involves several entities and must be enabled as batch mode in the customer engagement app, dual-write expects the relationships to be identified and defined on the entity. The following illustration shows the relationship between Sales Order header V2 and Sales Order Line V2.

To help prevent performance issues, avoid using a large number of data sources in dual-write data tables that raise multiple events for a record change. Don’t map unwanted fields in dual-write, and avoid excessive business logic on tables and entities.

If a custom entity in the Finance and Operations app is company-specific (that is, the primary company context property of the entity is set to DataAreaId, as shown in the following illustration), the related Dataverse table should have a company lookup as one of the key columns. Mapping between the shared entity and the company-specific entity isn’t allowed. You can determine whether a Finance and Operations app entity is shared or company-specific by looking at the entity property in Visual Studio Application Explorer. For more information, see Cross company behavior of Data entities.

Filter guidance for maps

You can apply filters to both Finance and Operations entities and Dataverse tables. Filters should be applied only on fields that are present on the dual-write maps. Verify the filter results before you add them to dual-write maps.

For Finance and Operations entities, you can verify filter expressions by using the following code example in an X++ runnable class. Replace the expression and the entity name, and run the class.
```javascript
var entityName = "PROJECTENTITY";
var filterExpression = '(ParentProject == "")';
Query query = new Query();
query.literals(NoYes::Yes);
QueryBuildDataSource qbd = query.addDataSource(tablename2id(entityName));
qbd.addRange(fieldname2id(qbd.table(),identifierStr(RecVersion))).
  value(filterExpression);
qbd.addSelectionField(fieldname2id(qbd.table(),identifierStr(RecId)));
QueryRun qRun = new QueryRun(query);
// This provides the actual SQL statement to execute
var actualSqlStatement = query.getSQLStatement();
while(qRun.next())
{
  var rec = qRun.get(tableName2Id(entityName));
}

For Dataverse tables, you can verify filter expressions by adding the expression as a filter condition on the OData expression.

https://<Env URL>/api/data/v9.0/<TableName>?$filter=<fieldname> eq <value>

For more information about filters, and more examples, see Examples and patterns for filtering.
```
This article describes how to select multiple table maps, view a list of dependent table maps, enable the table maps and all of its related tables, and copy pre-existing data.

As part of day to day operations, there may be a need to bulk handle table maps. For example, you may want to simultaneously enable or pause a set of table maps. Instead of doing this one by one, which is cumbersome and time consuming, you can now enable, pause, resume, or stop more than one table map at the same time in the dual-write list page.

As part of enabling multiple table maps, you also get to view the list of all the dependent table maps by selecting **Show related table map(s)**.

To enable the selected table map and all its related tables, select **Run**. If you want to copy the pre-existing data
for the selected table maps or its dependents, select the corresponding Initial sync check box. Alternatively, remove one or more of the related tables by clearing the corresponding check box. You can also drag and drop the table maps to change the order in which the maps will be synced.
The dual-write wizard enables you to add or remove a company or legal entity after dual-write has been set up. You can do this without having to unlink and relink your dual-write environment.

The wizard enables you to link your Finance and Operations apps to Dataverse environments. As part of this wizard, you also can select one or more companies or legal entities. The company or legal entity list doesn’t remain static and is constantly changing. This is because you may need to add new companies, especially as part of a phased rollout or acquisitions. Until now, you were unable to add a company or legal entity without system down-time, which required you to unlink and relink your environment. All of this can be expensive, especially because of pre-existing data. With this feature, you can add a company in a live environment without the need to unlink your existing dual-write environment.

Add a company or legal entity after dual-write has been set up

Follow these steps to add a company or legal entity after dual-write has been set up.

1. On the Dual-write table map list page, select the Environment details button.

2. On the Legal entities tab, you see the company that you selected as part of the dual-write wizard to link environments. In this example, the company is USMF.
3. Select **Add legal entity** to add one or more companies to dual-write. In this example, GBSI. Select **Save**.

At this point, the legal entities start updating. The table maps that are currently running or paused go through the initial write process by copying pre-existing data. Until the process is completed, we recommend that you do not perform any actions to modify your table maps.
NOTE
This operation may fail if either of the following conditions are true:

- You add or remove a new company when one or more table maps is already in the Initial writes state. This the process where the system is copying pre-existing data.
- You remove a company when one or more table maps is in the Paused state.

4. After the process is complete, a banner displays informing you that the legal entities have been updated successfully. You can now resume updates to your table maps.
You can pause table maps, either manually or automatically via rules. By pausing table maps, you help ensure business continuity, especially during planned or unplanned maintenance. While the app is being maintained, users can continue to do their work and create records.

When you pause a table map that is in the **Running** state, all records that have been created or updated are queued until you resume the table map. The queued records are stored in secure Microsoft Azure storage. They are then played back when you resume the table map and put it back into the **Running** state.

**NOTE**

While a table map is in the **Paused** state, there are limits on the number of records that you can queue and the amount of time that you can queue them for. Whichever limit occurs first will apply. The process starts with soft limits and eventually enforces harder limits to help protect you from exceeding the storage limits.

Records that have been created or updated for a table map that is in the **Paused** state can be viewed on the **Queued records** tab for each table map.

The **Total queued record count** line shows the total number of records that have been queued for a given table map. You can select **Load more** to view additional records in the paginated view. You can also filter the records by the integration key.

When you resume the table map, its state is changed from **Paused** to **Running**, and the records are written from the queue to the destination app. Some records might error out and fail to be written for various reasons, such as business validations in the destination app. In these cases, the records will remain in the queue and can be viewed on the **Catch-up errors** tab. For more information, see Catch-up errors from pausing a table map.
Microsoft has invested lots of time and effort into making dual-write resilient to errors. However, if you encounter an issue while or after you enable table maps for dual-write, you can select specific table maps to get a consolidated view of all the activities and errors for them. This consolidated view includes error logs. The goal is to help you during troubleshooting by providing a single view of the activities for a table map.

Consolidated error management

The activity log provides a chronological list of events that a specific table map goes through from the Not Running status to the Running status. For example, the list can include mappings that are created, updates of column mappings, and mappings that are run. Additionally, if errors occur, you can download the logs to get the next level of details.

Re-running execution for Initial sync

If you encounter issues while you copy pre-existing data between Finance and Operations apps and Dataverse, the Initial sync details tab provides a count of the errors.

Clicking on the individual project will show you the direction in which the sync failed (Finance and Operations app to Dataverse or vice-versa) and details of why it failed. You can choose to fix the underlying issues and then select Re-run execution which retries the entire execution, along with the records that failed or errored out in the last sync. Once this completes, initial sync is completed and the table returns to the Running state. There may be cases where you want to ignore the errors and add new incremental data. In these cases, you can select Rerun execution without errors, which lets you add new data and not retry the errored records.
Catch-up errors from pausing a table map

When you resume a table map after pausing, some records might error out and fail to write due to various reasons including business validations on destination app. In these cases, the records will continue to remain in the queue and can be viewed under the Catch-up errors tab.

The detailed Error message will help you fix the underlying issue after which you could Retry selected records or Retry All records. Once the retry is successful, Retry status will be marked as Completed.
Alert notifications

As an admin, you can create one or more alert settings to handle cases of planned or unplanned maintenance. For example, you can set up the dual-write system to notify you by email if a specific error threshold is reached because of, for example, network errors. The dual-write system can also take action on your behalf. For example, it can pause or stop dual-write.

The following illustration shows an example where dual-write will be paused if 10 errors of the Application error type occur within 15 minutes.

By selecting Create alert settings, you can create more alerts. You can also select whether notifications should be sent to an individual or a group, and whether the dual-write system should take any action on your behalf. To send alerts to a group, enter the values separated by commas, for example, "id1@contoso.com, id2@contoso.com".

---

NOTE

Errored records will be available in the queue for 7 days after which will the queue will be purged. In some cases, you may no longer need these records and they can be deleted from the queue.
In order for your alerts to take effect, you need to restart your table maps

This feature is especially useful if there is unplanned maintenance. For example, one of the apps becomes unavailable and, based on your defined thresholds, dual-write goes into a paused state where all new requests are queued (that is, they aren’t lost). After you fix the underlying issue, and both apps are running smoothly, you can resume from the paused state. The updates will then be read back from the queue and written to the recovered app.

**Next steps**

Application lifecycle management
By making dual-write solution-aware, you enable basic application lifecycle management (ALM) capabilities, such as transportation and backup/restore of dual-write table maps across environments. You also enable scenarios where you can get solutions that are published by Microsoft or an independent software vendor (ISV) from AppSource.

What is a dual-write solution?

A dual-write solution can contain one or more dual-write table maps. These maps can be imported into your environment (by selecting Solutions in Microsoft Power Apps). They can also be exported to other environments as a package. You can import Microsoft-published or ISV-published table maps from AppSource, modify them in your test environment, test them, and then, when they are ready, export them to your production environment. Additionally, you can publish your solution through AppSource, so that other people can use it.

There are two types of solutions: managed and unmanaged.

A managed solution can’t be modified, and it can be uninstalled after it’s imported. When you import an unmanaged solution, you add all the components of that solution into your environment. When you import an unmanaged solution that contains components that you’ve already customized, your customizations are overwritten by the customizations in the imported unmanaged solution.

For more information about solutions, see the solutions overview.

Install the dual-write core solution

The dual-write core solution contains metadata for your table maps and must be installed in your environments.

1. In Power Apps, in the left pane, select Solutions.
2. Select Open AppSource, and search for the solution that is named Dual Write Core.
3. Follow the prompts to import the solution.
Install the dual-write table maps solution

1. In Power Apps, in the left pane, select **Solutions**.

2. Select **Open AppSource**, and search for the solution that is named **Dataverse Add-in for Finance and Operations package**.

3. Follow the prompts to import the solution.

4. In the Finance and Operations app, on the **Dual-write** page, select **Apply Solution** to apply the table maps that you downloaded and installed. After you apply the solution, you will see that the default table maps are published.

![Apply Solution](image)

You've now successfully imported and applied a Microsoft-published dual-write table maps solution to your environment.

Import table maps through a dual-write solution and apply them to your environment (New environments)

This section explains how to import table maps from AppSource and apply them to your environment.

1. Import the dual-write core solution.
   
a. Create a new dual-write environment (a Finance and Operations app environment and a Dataverse environment).
   
b. Follow the instructions in the **Install the dual-write core solution** section earlier in this topic to install the dual-write core solution from AppSource in Power Apps.
   
c. Verify that the dual-write core solution is listed under **Solutions** in Power Apps.

2. Import the Microsoft-published or ISV-published table maps solution.
a. Follow the instructions in the Install the dual-write table maps solution section to download and install the Microsoft-published or ISV-published table maps from AppSource in Power Apps.

b. Verify that the table maps solution is listed under Solutions in Power Apps.

3. Apply the dual-write table maps solution to your Finance and Operations app environment.

   Apply the solution that you downloaded by selecting Apply Solutions on the Dual-write page in the Finance and Operations app, as described in the Install the dual-write table maps solution section.

Update table maps and export them to other environments as a solution

This section explains how to export your customized table maps as a solution, use it as a backup, and move the artifacts across environments and/or publish them to AppSource.

Customize your table maps

The first step is to customize your table maps by modifying existing table maps and adding a new table map.

1. In the Finance and Operations app, on the Table mappings tab, customize the mappings for the default table map that you just installed by using a solution. To add a new table map, select Add Table. In both cases, when you save the table map, you're prompted to specify the publisher and the version number.

   The following figure shows how to add a new column that is named birthday to the contacts - CDS Contacts V2 table map and select the default publisher.
NOTE
When you create a new solution by using these modified table maps, you must specify the same publisher.

The following figure shows how to add a new table map that is named Address books.

2. Confirm the table maps that you just modified and added. Be sure to enable and test them, to ensure that they work as you expect.
Create a new dual-write solution and add your components (Customized table maps)

Now that you’ve customized your mappings and added new mappings, the next step is to create a new dual-write solution and add the table maps to it.

1. In Power Apps, in the left pane, select **Solutions**, and then select **New solution** to create a solution. For this example, the solution is named **MyCustomTableMaps**. Be sure to select the same publisher that you selected in previous steps.

2. Select **Create**. The new solution appears on the **Solutions** list page.
3. Now that you've created your dual-write solution, you can add the customized table maps that you created in previous steps. Select the MyCustomTableMaps solution that you just created, select Add existing, point to Other, and then select Dual Write table map.

4. In the list, select the customized table maps, and add them to the solution. The solution should now contain your customized tables.

You've now customized your tables and put them into a solution.

Export and publish your solution
After you run the solution checker and make sure that there are no issues, you export the solution that you created and publish the changes.

1. In the list of solutions, select your solution, and then select Export.
2. Update the version number, and select whether you want to export the solution as a managed or unmanaged solution. (We recommend that you export it as a managed solution.) Then select Export.

3. Before you export, select Publish all changes, and then select Check for issues. When you’ve finished, select Next to publish all your changes.

The solution, together with all its components, is exported to a zip file.
You've now customized your tables, added them to a new solution, and created a solution file that can be imported and applied to other environments. (This capability can be useful if you want to move table maps between test and production environments.) In a similar way, you can create a backup of all your table maps by adding them to a solution and exporting the solution as a package. That package can then be imported into any environment to restore the table maps.

For information about how to publish the package to AppSource, see Publish your app on AppSource.

**Test your exported solution package**

You can test your exported solution package by importing and applying it to another environment.

1. In Power Apps, select **Import** to import the package into a new environment.

2. Apply the solution that you just imported to the environment.
3. Verify that the two customized table maps appear on the dual-write table maps list page.

4. Make sure that the customizations from previous steps are preserved.
Use the table map version

Sometimes, a solution might contain different implementations of a table map. For example, the version of the contacts - CDS Contacts V2 table map might have a different publisher or a newer version number. In these cases, you can use the Table Map version button to select which table map you want to use in your environment.

Upgrade existing dual-write environments for solution awareness (Existing environments)

1. Import the dual-write core solution.
   a. Follow the instructions in the Install the dual-write core solution section earlier in this topic to import the dual-write core solution from AppSource into Power Apps.
   b. Verify that the dual-write core solution is listed under Solutions in Power Apps.
2. Upgrade the table maps.
   You’ll see a notification prompting you to upgrade.
Select Upgrade table maps at the top of the page.

The upgrade takes a few minutes. When it's completed, you receive a notification.
In Finance and Operations apps, global tables are not associated with a company or legal entity. For these tables, you can specify a team and not use a default team as owner when writing to Microsoft Dataverse using dual-write.

By default, when you enable dual-write, the root business unit’s default team will become the default owner for all rows integrated through dual-write. This may not be what you want when you want to limit access to these records to just a subset of users. It’s not uncommon for an organization to have multiple departments defined by business units with corresponding teams under them. You don’t want all users of the default team to have access to all the records integrated via dual-write. In these situations, you can specify a different team for each global table as an owner for these records.

**Change the owning team**

When you select a global table map such as Global Products, under Table mappings, you can view the list of teams in the Update owning team section. By default, dual-write uses the default team, which is indicated by a blank value. After you create a new map with a new version, you change the default behavior by picking a new team from the owning team list and then save the new value. The **Owning team** field is shown in the following screenshot.

![Screenshot showing the owning team field](image)

After you set the owning team, it works across both initial and live sync. The owning team setting does not transfer across environments.

**NOTE**

After you set the owning team, it works across both initial and live sync. The owning team setting does not transfer across environments.
View the owning team after initial sync

After you run the initial sync, the owner is shown in the integrated records. In the following screenshot, the owner has changed from **dwteam** to **Sales** for the integrated records in **Global Product** table map.
When you unlink and relink dual-write connection between environments, you need to delete the data from the key tables. This requirement applies to sandbox, production, and user acceptance test (UAT) environments during activities like backup and restore. This topic describes how to unlink, delete the data in the key tables, and then relink the dual-write environments.

The mappings are preserved when you unlink and relink, because the mappings are stored in Dataverse.

**Scenario: Dual-write is enabled between production environments**

In this scenario, dual-write is enabled between Finance and Operations and Dataverse production environments. You want to back up the Finance and Operations production environment (source) and restore it to Finance and Operations UAT environment (destination). Once you restore, follow these steps on the Finance and Operations UAT environment:

1. Stop all table maps.
2. Unlink the dual-write connection as the Finance and Operations UAT environment will be pointing towards Dataverse production environment.
3. Delete the data from the key tables:
   - **DualWriteProjectConfiguration**
   - **DualWriteProjectFieldConfiguration**
   - **BusinessEventsDefinition**
4. You may want to relink Finance and Operations UAT environment against Dataverse UAT environment.
5. Enable the maps.

If the backup and restore processes are running on Dataverse, then follow these steps:

1. Sign in to Finance and Operations UAT environment.
2. Stop all table maps.
3. Unlink the dual-write connection as the Dataverse UAT environment will be pointing towards Finance and Operations production environment.
4. Delete the data from the **Dual Write Runtime Configurations** table on Dataverse.
5. You may want to relink Finance and Operations UAT environment against Dataverse UAT environment.
6. Enable the maps.

**Scenario: Reset or change linking**

If you want to reset your existing sandbox Dataverse instance that is linked for dual-write or you want to change the linking to a different Dataverse instance, then follow these steps:

1. Sign in to the Finance and Operations app.
2. Stop all entity maps.
3. Unlink the dual-write connection between Finance and Operations app and Dataverse.
4. Reset the Dataverse environment.
5. Delete the data from the key tables in the Finance and Operations app.
   - DualWriteProjectConfiguration
   - DualWriteProjectFieldConfiguration
   - BusinessEventsDefinition

6. Set up dual-write on the environment that you want to reset. For more information, see System requirements and prerequisites.

Known issues

SecureConfig Organization error
When you try to copy, update, or delete records after copying the environment, the following error appears:
SecureConfig Organization (ProjOpsTest4) does not match actual CRM Organization (org6459f7a8_195867911_20200717T174709).

Follow these steps to mitigate the error:

1. In the customer engagement app, select Advanced find.
2. In the Look for field, select Dual Write Runtime Configurations.
3. Select Results.
4. Rows will be displayed. Select all the rows.
5. Select the Delete icon.
Customer data can be mastered in more than one Dynamics 365 application. For example, a customer row can originate through sales activity in Dynamics 365 Sales (a customer engagement app), or a row can originate through retail activity in Dynamics 365 Commerce (a finance and operations app). No matter where the customer data originates, it is integrated behind the scenes. Integrated customer master gives you the flexibility to master customer data in any Dynamics 365 application and provides a comprehensive view of the customer across the Dynamics 365 application suite.

Customer data flow

*Customer* is a well-defined concept in applications. Therefore, the integration of customer data just involves harmonizing the customer concept between the two applications. The following illustration shows the customer data flow.

Customers can be broadly classified into two types: commercial/organizational customers and consumers/end users. These two types of customers are stored and handled differently in Finance and Operations and Dataverse.

In Finance and Operations, both commercial/organizational customers and consumers/end users are mastered in a single table that is named `CustTable` (CustCustomerV3Entity), and they are classified based on the `Type` attribute. (If `Type` is set to `Organization`, the customer is a commercial/organizational customer, and if `Type` is set to `Person`, the customer is a consumer/end user.) The primary contact person information is handled through the SMMContactPersonEntity table.

In Dataverse, commercial/organizational customers are mastered in the Account table and are identified as customers when the `RelationshipType` attribute is set to `Customer`. Both consumers/end users and the contact person are represented by the Contact table. To provide a clear separation between a consumer/end user and a contact person, the `Contact` table has a Boolean flag that is named `Sellable`. When `Sellable` is `True`, the contact is a consumer/end user, and quotations and orders can be created for that contact. When `Sellable` is `False`, the contact is just a primary contact person of a customer.
When a non-sellable contact participates in a quotation or order process, **Sellable** is set to **True** to flag the contact as a sellable contact. A contact that has become a sellable contact remains a sellable contact.

**Templates**

Customer data includes all information about the customer, such as the customer group, addresses, contact information, payment profile, invoice profile, and loyalty status. A collection of table maps works together during customer data interaction, as shown in the following table.

<table>
<thead>
<tr>
<th>FINANCE AND OPERATIONS APPS</th>
<th>CUSTOMER ENGAGEMENT APPS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDS Contacts V2</td>
<td>contacts</td>
<td>This template synchronizes all primary, secondary, and tertiary contact information, for both customers and vendors.</td>

</tbody>
</table>
The term vendor refers to a supplier organization, or a sole proprietor who supplies goods or services to a business. Although vendor is an established concept in Microsoft Dynamics 365 Supply Chain Management, no vendor concept exists in customer engagement apps. However, you can overload the Account/Contact table to store vendor information. The integrated vendor master introduces an explicit vendor concept in customer engagement apps. You can either use the new vendor design or store vendor data in the Account/Contact table. Dual-write supports both approaches.

In both approaches, the vendor data is integrated between Dynamics 365 Supply Chain Management, Dynamics 365 Sales, Dynamics 365 Field Service, and Power Apps portals. In Supply Chain Management, the data is available for workflows such as purchase requisitions and purchase orders.

**Vendor data flow**

If you don’t want to store vendor data in the Account/Contact table in Dataverse, you can use the new vendor design.

If you want to continue to store vendor data in the Account/Contact table, you can use the extended vendor design. To use the extended vendor design, you must configure the vendor workflows in the dual-write solution package. For more information, see Switch between vendor designs.
If you’re using Power Apps portals for self-service vendors, the vendor information can flow directly to Finance and Operations apps.

**Templates**

Vendor data includes all information about the vendor, such as the vendor group, addresses, contact information, payment profile, and invoice profile. A collection of table maps work together during vendor data interaction, as shown in the following table.

Vendor data flow

If you choose to use the Account table to store vendors of the Organization type and the Contact table to store vendors of the Person type, configure the following workflows. Otherwise, this configuration isn’t required.

Use the extended vendor design for vendors of the Organization type

The Dynamics365FinanceExtended solution package contains the following workflow process templates. You will create a workflow for each template.

- Create Vendors in Accounts Table
- Create Vendors in Vendors Table
- Update Vendors in Accounts Table
- Update Vendors in Vendors Table

To create new workflow processes by using the workflow process templates, follow these steps.

1. Create a workflow process for the Vendor table, and select the Create Vendors in Accounts Table workflow process template. Then select OK. This workflow handles the vendor creation scenario for the Account table.

2. Create a workflow process for the Vendor table, and select the Update Vendors in Accounts Table workflow process template. Then select OK. This workflow handles the vendor update scenario for the
3. Create a workflow process for the **Account** table, and select the Create Vendors in Vendors Table workflow process template.

4. Create a workflow process for the **Account** table, and select the Update Vendors in Vendors Table workflow process template.

5. You can configure the workflows as either real-time workflows or background workflows, depending on your requirements. To configure a workflow as a background workflow, select *Convert to a background workflow*.

6. Activate the workflows that you created for the **Account** and **Vendor** tables to start to use the **Account** table to store information for vendors of the **Organization** type.

**Use the extended vendor design for vendors of the Person type**

The **Dynamics365FinanceExtended** solution package contains the following workflow process templates. You will create a workflow for each template.

- Create Vendors of type Person in Vendors Table
- Create Vendors of type Person in Contacts Table
- Update Vendors of type Person in Contacts Table
- Update Vendors of type Person in Vendors Table

To create new workflow processes by using the workflow process templates, follow these steps.

1. Create a workflow process for the **Vendor** table, and select the Create Vendors of type Person in Contacts Table workflow process template. Then select *OK*. This workflow handles the vendor creation scenario for the **Contact** table.

2. Create a workflow process for the **Vendor** table, and select the Update Vendors of type Person in Contacts Table workflow process template. Then select *OK*. This workflow handles the vendor update scenario for the **Contact** table.

3. Create a workflow process for the **Contact** table, and select the Create Vendors of type Person in Vendors Table template.

4. Create a workflow process for the **Contact** table, and select the Update Vendors of type Person in Vendors Table template.
5. You can configure the workflows as either real-time workflows or background workflows, depending on your requirements. To configure a workflow as a background workflow, select Convert to a background workflow.

6. Activate the workflows that you created on the Contact and Vendor tables to start to use the Contact table to store information for vendors of the Person type.
Businesses classify customers and provide sophisticated services, based on customer shopping and spending patterns. For example, Dynamics 365 Commerce has the infrastructure and functions to facilitate and handle customer loyalty cards, reward points, loyalty-based pricing, and rewards-based shopping experiences. When data about customer loyalty cards and reward points in Commerce is synced to Dataverse, customer engagement apps can use that data. For example, Dynamics 365 Customer Service users can use the data to provide the same sophisticated services through the help desk.

When a business ecosystem is made up of Dynamics 365 applications, such as Finance, Supply Chain Management, and Sales, businesses often use these applications to source product data. This is because these apps provide a robust product infrastructure complemented with sophisticated pricing concepts and accurate on-hand inventory data. Businesses who use an external Product Lifecycle Management (PLM) system for sourcing the product data can channelize products from Finance and Operations apps to other Dynamics 365 apps. The unified product experience brings the integrated product data model in to Dataverse, so that all application users, including Power Platform users, can take advantage of the rich product data coming from Finance and Operations apps.

Here is the product data model from Sales.

Here is the product data model from Finance and Operations apps.
These two product data models have been integrated in Dataverse as shown below.

The dual-write table maps for products have been designed to flow data one-way only, in near-real time from Finance and Operations apps to Dataverse. However, the product infrastructure has been made open to make it bi-directional if required. Although you can customize it, it's at your own risk, as Microsoft does not recommend this approach.

**Templates**

Product information contains all the information related to the product and its definition, such as the product dimensions or the tracking and storage dimensions. As the following table shows, a collection of table maps is created to sync products and related information.
<table>
<thead>

<td>The <em>Shared product color</em> table indicates the colors that a specific product master can have. This concept is migrated to Dataverse to keep data consistent.</td>
</tr>
</tbody>
</table>
The **Shared product configuration** table indicates the configurations that a specific product master can have. This concept is migrated to Dataverse to keep data consistent.

The **Shared product size** table indicates the sizes that a specific product master can have. This concept is migrated to Dataverse to keep data consistent.

The **Shared product style** table indicates the styles that a specific product master can have. This concept is migrated to Dataverse to keep data consistent.

Product bar codes are used to uniquely identify products.

The **msdyn_sharedproductdetails** table contains the columns from Finance and Operations apps that define the product, and that contain the product's financial and management information.

The product storage dimension group represents the method used to define the placement the product in the warehouse.

The product tracking dimension group represents the method used to track the product in inventory.

Integration of products

In this model, the product is represented by the combination of two tables in Dataverse: **Product** and **msdyn_sharedproductdetails**. Whereas the first table contains the definition of a product (the unique identifier for the product, the product name, and the description), the second table contains the columns stored at the product level. The combination of these two tables is used to define the product according to the concept of the stockkeeping unit (SKU). Each released product will have its information in the mentioned tables (Product
and Shared Product Details). To keep track of all products (released and not released), the Global products table is used.

Because the product is represented as a SKU, the concepts of distinct products, product masters, and product variants can be captured in Dataverse in the following way:

- **Products with subtype product** are products that are defined by themselves. No dimensions have to be defined. An example is a specific book. For these products, one row is created in the Product table, and one row is created in the msdyn_sharedproductdetails table. No product family row is created.

- **Product masters** are used as generic products that hold the definition and rules that determine the behavior in business processes. Based on these definitions, distinct products that are known as product variants can be generated. For example, T-shirt is the product master, and it can have Color and Size as dimensions. Variants can be released that have different combinations of these dimensions, such as a small blue T-shirt or a medium green T-shirt. In the integration, one row per variant is created in the product table. This row contains the variant-specific information, such as the different dimensions. The generic information for the product is stored in the msdyn_sharedproductdetails table. (This generic information is held in the product master.) The product master information is synced to Dataverse as soon as the released product master is created (but before variants are released).

- **Distinct products** refer to all the products subtype product and all the product variants.

**Model-driven apps in Dynamics 365**

**Finance and Operations apps**

With the dual-write functionality enabled, the products from Finance and Operations will be synchronized in other Dynamics 365 products in Draft state. They are added to the first price list with the same currency used in the customer engagement app and using alphabetical sort on the price list name. In other words, they are added to the first price list in a Dynamics 365 app that matches the currency of your legal table where the product is released in a Finance and Operations app. If there is no price list for the given currency, a price list will automatically be created and the product will be assigned to it.

The current implementation of the dual-write plugins that associate the default price list to the unit look the currency associated with the Finance and Operations app and find the first price list in the customer engagement app using alphabetical sort on the price list name. To set a default price list for a specific currency
when you have multiple price lists for that currency, you must update the price list name to a name that is earlier in alphabetical order than any other price lists for that same currency. If it does not have any price list for the given currency, a new one is created.

By default products from Finance and Operations apps are synchronized to other Dynamics 365 apps in Draft state. To synchronize the product with Active state so that you can directly use it in sales order quotations, for example, the following setting needs to be chosen: System > Administration > System administration > System settings > Sales tab and select Create products in active state = yes.

When products are synchronized, you must enter a value for the Sales unit field in the Finance and Operations app, because it is a mandatory field in Sales.

The creation of product families from Dynamics 365 Sales is not supported with the dual-write synchronization of products.

The synchronization of products happens from the Finance and Operations app to Dataverse. This means that the values of the product table columns can be changed in Dataverse, but when the synchronization is triggered (when a product column is modified in a Finance and Operations app), this will overwrite the values in Dataverse.

<td>msdyn_globalproducts</td>
</tr>
</tbody>
</table>

Product dimensions

Product dimensions are characteristics that identify a product variant. The four product dimensions (Color, Size, Style, and Configuration) are also mapped to Dataverse to define the product variants. The following illustration shows the data model for the product dimension Color. The same model is applied to Sizes, Styles and Configurations.
When a product has different product dimensions (for example, a product master has Size and Color as product dimensions), each distinct product (that is, each product variant) is defined as a combination of those product dimensions. For example, product number B0001 is an extra-small black T-shirt, and product number B0002 is a small black T-shirt. In this case, the existing combinations of product dimensions are defined. For example, the T-shirt from the preceding example can be extra-small and black, small and black, medium and black, or large and black, but it can't be extra-large and black. In other words, the product dimensions that a product master can take are specified, and variants can be released based on these values.

To keep track of the product dimensions that a product master can take, the following tables are created and mapped in Dataverse for each product dimension. For more information, see Product information overview.

### Default order settings and product-specific default order settings

Default order settings define the site and warehouse where items will be sourced from or stored, the minimum, maximum, multiple and standard quantities that will be used for trading or inventory management, the lead times, the stop flag, and the order promising method. This information is available in Dataverse using the default order settings and product-specific default order settings entity. You can read more information about the functionality in the Default order settings topic.

### Unit of measure and unit of measure conversions

The units of measure and its respective conversion are available in the Dataverse following the data model shown in the diagram.
The unit of measure concept is integrated between Finance and Operations apps and other Dynamics 365 apps. For each unit class in a Finance and Operations app, a unit group is created in a Dynamics 365 app, which contains the units belonging to the unit class. A default base unit is also created for every unit group.

<table>

</tbody>
</table>

**Initial synchronization of units data matching between Finance and Operations and Dataverse**

**Initial synchronization of units**

When dual write is enabled, units from Finance and Operations apps are synchronized to other Dynamics 365 apps. The unit groups synchronized from Finance and Operations apps in Dataverse have a flag set that indicates they are "Externally maintained".

**Matching units and unit classes/groups data from Finance and Operations and other Dynamics 365 apps**

First, it’s important to note that the integration key for unit is msdyn_symbol. Therefore, this value must be unique in Dataverse or other Dynamics 365 apps. Because in other Dynamics 365 apps it is the pair “Unit group ID” and “Name” that define the uniqueness of a unit, you need to consider different scenarios for matching unit data between Finance and Operations apps and Dataverse.

For units matching/overlapping in Finance and Operations apps and other Dynamics 365 apps:

- The unit belongs to a unit group in other Dynamics 365 apps that corresponds to the

associated unit class in Finance and Operations apps. In this case, the column msdyn_symbol in other Dynamics 365 apps must be filled in with the unit symbol from Finance and Operations apps. Therefore, when the data will be matched, and the unit group will be set as "Externally maintained" in other Dynamics 365 apps.

- The unit belongs to a unit group in other Dynamics 365 apps that does not correspond to the associated unit class in Finance and Operations apps (no existing unit class in Finance and Operations apps for the unit class in other Dynamics 365 apps). In this case, the msdyn_symbol must be filled in with a random string. Note that this value must be unique in other Dynamics 365 apps.

For units and unit classes in Finance and Operations not existing in other Dynamics 365 apps:

As part of dual-write the unit groups from Finance and Operations apps and its corresponding units are created and synchronized in other Dynamics 365 apps and Dataverse and the unit group will be set as "Externally maintained". No extra bootstrapping effort is required.

For units in other Dynamics 365 apps that do not exist in Finance and Operations apps:

The column msdyn_symbol must be filled in for all units. The units can always be created in Finance and Operations apps in the corresponding unit class (if it exists). If the unit class doesn’t exist, first the unit class must be created (note that you cannot create a unit class in Finance and Operations apps except through extension if you are extending the enum) matching the other Dynamics 365 apps unit group. Then you can create the unit. Note that the unit symbol in Finance and Operations apps must be the msdyn_symbol previously specified in other Dynamics 365 apps for the unit.

Product policies: dimension, tracking and storage groups

The product policies are sets of policies used for defining products and its characteristics in inventory. The product dimension group, product tracking dimension group and storage dimension group can be found as product policies.

<table>

Integration key for products

To uniquely identify products between Dynamics 365 for Finance and Operations and products in Dataverse the integration keys are used. For products, the `(productnumber)` is the unique key that identifies a product in Dataverse. It’s composed by the concatenation of: `(company, msdyn_productnumber)`. The `company`
indicates the legal entity in Finance and Operations and `msdyn_productnumber` indicates the product number for the specific product in Finance and Operations.

For users of other Dynamics 365 apps, the product is identified in the UI with the `msdyn_productnumber` (note that the label of the column is *Product number*). In the product form both the company and the `msydnn_productnumber` are shown. However, the (productnumber) column, the unique key for a product, is not shown.

If you build apps on Dataverse, you should pay attention to using the `productnumber` (the unique product ID) as the integration key. Do not use `msdyn_productnumber`, because it’s not unique.

**Initial synchronization of products and migration of data from Dataverse to Finance and Operations**

**Initial synchronization of products**

When dual-write is enabled, products from Finance and Operations apps are synchronized to Dataverse and customer engagement apps. Products created in Dataverse and other Dynamics 365 apps before dual-write was released will not be updated or matched with product data from Finance and Operations apps.

**Matching product data from Finance and Operations and other Dynamics 365 apps**

If the same products are kept (overlapping/matching) in Finance and Operations and in Dataverse and other Dynamics 365 apps, when enabling dual-write the synchronization of products from Finance and Operations will take place, and duplicate rows will appear in Dataverse for the same product. To avoid the previous situation, if other Dynamics 365 apps have products that are overlapping/matching with Finance and Operations, then the administrator enabling dual write must bootstrap the columns *Company* (example: “USMF”) and `msdyn_productnumber` (example: “1234:Black:S”) before the synchronization of products takes place. In other words, these two columns in the product in Dataverse must be filled in with the respective company in Finance and Operations to which the product needs to be matched with and with its product number.

Then, when the synchronization is enabled and takes place, the products from Finance and Operations will be synchronized with the matched products in Dataverse and other Dynamics 365 apps. This is applicable for both distinct products and product variants.

**Migration of product data from other Dynamics 365 apps to Finance and Operations**

If other Dynamics 365 apps have products that aren’t present in Finance and Operations, the administrator can first use the `EcoResReleasedProductCreationV2Entity` for importing those products in Finance and Operations. And secondly, match the product data from Finance and Operations and other Dynamics 365 apps as described above.
This topic describes the integration of site and warehouse data between Finance and Operations and Dataverse. Operational sites and warehouses are common concepts in a Supply Chain Management application. They are used to model the supply chain of your company.

**Templates**

With the integration with Dataverse, these concepts and all their related information are available in Dataverse using the sites and warehouses data tables in the following table.

<table>
<thead>
<tr>
<th>FINANCE AND OPERATIONS APPS</th>
<th>CUSTOMER ENGAGEMENT APPS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sites</td>
<td>msdyn_operationalsites</td>
<td></td>
</tr>
<tr>
<td>Warehouses</td>
<td>msdyn_warehouses</td>
<td></td>
</tr>
</tbody>
</table>
In Finance and Operations, the concept of a *company* is both a legal construct and a business construct. It’s also a security and visibility boundary for data. Users always work in the context of a single company, and most of the data is striped by company.

Dataverse doesn’t have an equivalent concept. The closest concept is *business unit*, which is primarily a security and visibility boundary for user data. This concept doesn’t have the same legal or business implications as the company concept.

Because business unit and company aren’t equivalent concepts, it isn’t possible to force a one-to-one (1:1) mapping between them for the purpose of Dataverse integration. However, because users must, by default, be able to see the same rows in the application and Dataverse, Microsoft has introduced a new table in Dataverse that is named cdm_Company. This table is equivalent to the Company table in the application. To help guarantee that visibility of rows is equivalent between the application and Dataverse out of the box, we recommend the following setup for data in Dataverse:

- For each Finance and Operations Company row that is enabled for dual-write, an associated cdm_Company row is created.
- When a cdm_Company row is created and enabled for dual-write, a default business unit is created that has the same name. Although a default team is automatically created for that business unit, the business unit isn’t used.
- A separate owner team is created that has the same name. It’s also associated with the business unit.
- By default, the owner of any row that is created and dual-written to Dataverse is set to the “DW Owner” team that is linked to the associated business unit.

The following illustration shows an example of this data setup in Dataverse.

Because of this configuration, any row that is related to the USMF company will be owned by a team that is linked to the USMF business unit in Dataverse. Therefore, any user who has access to that business unit through a security role that is set to business unit–level visibility can now see those rows. The following example shows how teams can be used to provide the correct access to those rows.

- The “Sales Manager” role is assigned to members of the “USMF Sales” team.
- Users who have the “Sales Manager” role can access any account rows that are members of the same business unit that they are members of.
- The “USMF Sales” team is linked to the USMF business unit that was mentioned earlier.
Therefore, members of the "USMF Sales" team can see any account that is owned by the "USMF DW" user, which would have come from the USMF Company table in Finance and Operations.

As the preceding illustration shows, this 1:1 mapping between business unit, company, and team is just a starting point. In this example, a new "Europe" business unit is manually created in Dataverse as the parent for both DEMF and ESMF. This new root business unit is unrelated to dual-write. However, it can be used to give members of the "EUR Sales" team access to account data in both DEMF and ESMF by setting the data visibility to Parent/Child BU in the associated security role.

A final topic to discuss is how dual-write determines which owner team it should assign rows to. This behavior is controlled by the Default owning team column on the cdm_Company row. When a cdm_Company row is enabled for dual-write, a plug-in automatically creates the associated business unit and owner team (if it doesn’t already exist), and sets the Default owning team column. The admin can change this column to a different value. However, the admin can’t clear the column as long as the table is enabled for dual-write.

Company striping and bootstrapping

Dataverse integration brings company parity by using a company identifier to stripe data. As the following illustration shows, all company-specific tables are extended so that they have a many-to-one (N:1) relationship with the cdm_Company table.
For rows, after a company is added and saved, the value becomes read-only. Therefore, users should make sure that they select the correct company.

Only rows that have company data are eligible for dual-write between the application and Dataverse.

For existing Dataverse data, an admin-led bootstrapping experience will soon be available.

Autopopulate company name in customer engagement apps

There are several ways to auto-populate the company name in customer engagement apps.

- If you are a system administrator, you can set the default company by navigating to Advanced Settings > System > Security > Users. Open the User form, and in the Organization Information section, set the Company to default on Forms value.

- If you have Write access to the SystemUser table for the Business Unit level, then you can change the default company on any form by selecting a company from the Company drop-down menu.
Apply filtering based on the company context

To apply filtering based on the company context on your custom forms or on custom lookup columns added to the standard forms, open the form and use the Related Records Filtering section to apply the company filter. You must set this for each lookup column that requires filtering based on the underlying company on a given row. The setting is shown for Account in the following illustration.
Initialize company data

11/24/2021 • 4 minutes to read • Edit Online

**IMPORTANT**

Some or all of the functionality noted in this topic is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see Service update availability.

If you have an existing Microsoft Dataverse instance or Finance and Operations app instance that has business data, you might want to enable a dual-write connection against it. In this case, you must initialize the Dataverse data or Finance and Operations app data with company information before you enable dual-write. This initialization process is sometimes referred to as *bootstrapping*.

This topic includes sample scenarios that explain how to use Azure Data Factory to initialize data in Dataverse tables for dual-write. It doesn’t cover all tables, error handling scenarios, or lookups. Use this topic and template as a reference to set up your own Azure Data Factory pipeline to import data into Dataverse or update data in Dataverse.

**High-level scenario**

Consider the Customers table in a Finance and Operations app, and the Account table in Dataverse.

- Use initial write to copy reference and dependent tables, such as Company, Customer groups, and Terms of payment, from the Finance and Operations app to Dataverse.
- Use the Data management framework to export data from the Finance and Operations app in comma-separated values (CSV) format. For example, set up an export project in Data management to export customers from each company by using the DataAreaId field in the Finance and Operations app. This process is a one-time manual process.
- Use Azure Blob Storage to store the CSV files for lookup and transformation. Upload the CSV file for your Finance and Operations customers into Azure Blob Storage.
- Use Azure Data Factory to initialize data in Dataverse.

The following illustration shows the workflow.
This scenario is based on the following assumptions:

- The source data is in the Finance and Operations app.
- If an account exists in Dataverse, but it doesn’t exist in the Finance and Operations app, it won’t be initialized as part of this flow. Use DIXF or initial sync functionality based on the amount of data stored in Dataverse.
- All account records in the customer engagement apps have a natural key (account number) that matches the Finance and Operations natural key (`CustomerAccount`).
- Rows have a one-to-one (1:1) mapping across the apps.

**NOTE**

In both Finance and Operations apps and Dataverse, When a customer record is created, Party record gets created implicitly.

### Prerequisites

- **Azure subscription** – You have contributor access to an existing Azure subscription. If you don’t have an Azure subscription, create a free Azure account before you begin.
- **Azure storage account** – You have an Azure storage account. If you don’t have a storage account, follow the steps in Create an Azure storage account to create one.
- **Azure data factory** – Create an Azure Data Factory resource by following the steps in Create a data factory.
- **Finance and Operations app** – Use the Data management framework to export the data in CSV format. For more information, see Data management overview. In this template, customers are exported by using the `CustCustomerV3Entity` table.
- **Dynamics 365 Dataverse** – Use the credentials for the Dataverse admin user to initialize the data.
- **Dual-write** – Dual-write solutions are installed, and reference data is copied by using initial write.

### Deployment steps

**Set up an Azure storage account**

If you don’t have an Azure storage account, follow these steps in Create an Azure storage account to create one. In your storage account, create one container that is named `ce-data`. This container will store all data files. You can change the container in your datasets and pipelines as you require. Go to **Access keys**, and copy the
Deploy an Azure Data Factory template

1. Make a note of the name of the Azure data factory that you created.

2. Make a note of the connection string for the Azure storage account.

3. Make a note of the service URI of the Dataverse instance, and the admin user name and password.

   The following table shows the parameters that are required.

```
<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>DESCRIPTION</th>
<th>EXAMPLE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Factory name</td>
<td>The name of your data factory</td>
<td>BootstrapDataverseDataADF</td>
</tr>
<tr>
<td>Bootstrap blob storage account</td>
<td>The connection string for blob storage</td>
<td>The value that you copied when you created the storage account</td>
</tr>
<tr>
<td>Linked Service_connection string</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Bootstrap Dynamics 365 Linked Service_service Uri</td>
<td>The URI of the Dataverse instance</td>
<td><a href="https://contosod365.crm4.dynamics.com">https://contosod365.crm4.dynamics.com</a></td>
</tr>
<tr>
<td>Bootstrap Dynamics 365 Linked Service_properties_type Properties_username</td>
<td>The Dynamics 365 admin user's user ID</td>
<td><a href="mailto:adminservice@contoso.onmicrosoft.com">adminservice@contoso.onmicrosoft.com</a></td>
</tr>
<tr>
<td>Bootstrap Dynamics 365 Linked Service_password</td>
<td>The Dynamics 365 admin user's password</td>
<td>*******</td>
</tr>
</tbody>
</table>
```

4. Download the Azure Resource Manager (ARM) template file to your local directory.

5. In the Azure portal, go to Custom deployment.

6. Select Build your own template in the editor.

7. Select Load file, and find and select the ARM template file that you downloaded earlier. Then select Save.

8. Provide the required parameters, select Review, and then select Create.
After deployment, you will see **Pipelines**, **Datasets**, and **Data flows** sections in the list pane.
Run the process

1. In the Finance and Operations app, use the Data management framework to export data in CSV format. For more information, see Data management overview. In this template, customer data was exported from the CustCustomerV3Entity table. Set up CustCustomerV3Entity, and remove the FullPrimaryAddress field map from the mapping. Add the DataAreaId field to the CSV file. Rename the exported file 01-CustomersV3Export-Customers V3.csv, and upload it to the Azure storage account that you named ce-data.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

2. Download the sample customer file.

3. Run BootstrapAccountsPipeline from Azure Data Factory.
Because Dynamics 365 Finance is a financial system, *organization* is a core concept, and system setup starts with the configuration of an organization hierarchy. Business financials can then be tracked at the organization level and also at any level in the organization hierarchy.

Although Dataverse doesn't have the concept of an organization hierarchy, it does have a few loose concepts, such as total sales revenue. As part of Dataverse integration, the organization hierarchy data structure is added to Dataverse.

**Data flow**

A business ecosystem that consists of Finance and Operations apps and Dataverse will continue to have an organization hierarchy. This organization hierarchy is built on Finance and Operations apps, but it's exposed in Dataverse for informational and extensibility purposes. The following illustration shows the organization hierarchy information that is exposed in Dataverse as a one-way data flow from Finance and Operations apps to Dataverse.

Organization hierarchy table maps are available for one-way synchronization of data from Finance and Operations apps to Dataverse.

**Templates**

Product information contains all the information related to the product and its definition, such as the product dimensions or the tracking and storage dimensions. As the following table shows, a collection of table maps is created to sync products and related information.

<table>
<thead>
<tr>

</tbody>
</table>

**Internal Organization**

Internal organization information in Dataverse comes from two tables, *Operating unit* and *Legal entities*. 
Every business works with a basic set of financial data, such as the fiscal calendar year, the currency that business is transacted in, the accounts that the money to run the business comes in to or goes out of, tax rates, and remittance. This data resides in Finance and Operations apps. However, it's exposed to Dataverse so that customer engagement apps can have a single source for finance and tax data. In this way, data is uniform across the business ecosystem.

Finance and tax data is integrated by using the following mappings:

- Integrated ledger
- Integrated tax master
In a business application, ledger data defines the core set up for how a company does business. For example, ledger data describes the fiscal year the company follows, the currencies it transacts in, and the accounts it uses. This topic describes the integration of this core financial data.

### Templates

Ledger data includes a collection of core financial table maps that work together during data interaction, as shown in the following table.

<table>

</table>
Microsoft Dynamics 365 Supply Chain Management provides robust procurement functionality. Dynamics 365 Field Service offers similar functionality that supports the purchasing processes that are associated with the service process. The functionality in these two apps is integrated through dual-write, and the resulting cross-functional use cases are enabled through table mappings, solution logic, views, and forms.

This integration supports purchase order creation and, in most cases, updates from both apps. However, Supply Chain Management controls pricing, addresses, and product receipt. Several powerful cross-functional use cases are enabled for organizations that use both Field Service and Supply Chain Management. These use cases enable procurements to be initiated and tracked across both systems.

The following illustration shows the tables in both systems and how they are mapped to each other. Purchase orders in Field Service reference an account row, whereas purchase orders in Supply Chain Management reference a vendor row. To resolve the integration, dual-write uses a reference to link vendor rows with account rows. For more information, see Integrated vendor master.

---

**Prerequisites**

To integrate Supply Chain Management with Field Service, you must install the following components:

- Field Service version 8.8.31.60 or later, for comprehensive purchase order integration
- Supply Chain Management version 10.0.14 or later
- Dual-write, to run the OneFSSCM solution

---

**Installation guidelines**

**Prerequisites**
- **Dual-write** – For more information, see the [Dual-write home page](#).
- **Dynamics 365 Field Service** – For more information, see [How to install Dynamics 365 Field Service](#).

When they are enabled in Microsoft Dataverse, dual-write and Field Service introduce several solution layers that extend the environment with new metadata, forms, views, and logic. These solutions can be enabled in any order, though you typically install in the order that is given here:

1. **Field Service Common** – Field Service Common is installed when Field Service is installed in the environment.
2. **Field Service (Anchor)** – Field Service (Anchor) is installed when Field Service is installed in the environment.
3. **Supply Chain Management Extended** – Supply Chain Management Extended is automatically installed when dual-write is enabled in an environment.
4. **OneFSSCM solution** – OneFSSCM is automatically installed by whichever solution (Field Service or Supply Chain Management) is installed last.
   - If Field Service is already installed in the environment, and you enable dual-write, which installs Supply Chain Management Extended, OneFSSCM is installed.
   - If Supply Chain Management Extended is already installed in the environment, and you install Field Service, OneFSSCM is installed.

**Initial synchronization**

To create new purchase orders and work with existing purchase orders, you must sync the reference data between Supply Chain Management and Dataverse. You use the initial write functionality to detect the table relationships and find the tables that you must enable for a given map.

You must sync the following tables:

- **Product templates**
  
  When you run the initial write, you get a full list of the tables that are required. Here are some examples of these templates:
  - All products
  - Released products V2
  - Dataverse released distinct products

- **Sites**

- **Warehouses**

- **Procurement categories templates**
  
  Here are some examples of these templates:
  - Procurement categories
  - Pro
  - Product category hierarchy
  - Product category assignments

- **Vendor templates, such as Vendor V2**

- **Contact person templates, such as Dataverse Contacts V2**

- **Worker templates, such as Worker**
Synchronization of the tables ensures that all documents (purchase orders and product receipts) in Supply Chain Management are available in Dataverse.

**Account and Vendor tables**

Purchase orders in Field Service rely on the Account table to track vendors. Therefore, the Dataverse tables for purchase orders use accounts to track vendors. To accommodate this key difference, the following four workflows must be activated to keep the accounts and vendors in sync:

- Create Vendors in Accounts table
- Create Vendors in Vendors table
- Update Vendors in Accounts table
- Update Vendors in Vendors table

If OneFSSCM is installed, because both Field Service and Supply Chain Management Extended are installed, these workflows are automatically activated. If Field Service isn’t installed, but you want to integrate the purchase order tables with Dataverse, you must activate these workflows. In both cases, unless you start from scratch, you might have to ensure that all vendors are created as accounts in Dataverse before you create purchase orders. Otherwise, errors might occur.

**Initial synchronization**

After all the prerequisites are in place, if you want existing purchase orders and product receipts to be available in both systems, you must do an initial synchronization of the following templates:

- Purchase Order Header V2
- CDS Purchase Order Line
- CDS Purchase Order Line soft delete
- Purchase Order Receipt
- Purchase Order Receipt Product

**Mappings with logic**

The procurement integration extends the product mapping with the following logic to ensure that the Field Service Product Type column is correctly set in the products table in Dataverse:

- If Product Type is set to Product, and Item model group, Stocked product is set to True, Field Service Product Type is set to Inventory.
- If Product Type is set to Product, and Item model group, Stocked product is set to False, Field Service Product Type is set to Non-Inventory.
- If Product Type is set to Service, Field Service Product Type is set to Service.

In addition, Dataverse includes logic that maps vendors with their related accounts. This logic sets the default invoice vendor account. On create, server-side plug-in logic sets the default invoice vendor account from the vendor that is related to the account. The vendor has a reference to the invoice account that is used to set this value.

**Supported scenarios**

- Purchase orders can be created and updated by Dataverse users. However, the process and data are controlled by Supply Chain Management. The constraints on updates to purchase order columns in Supply Chain Management apply when updates come from Field Service. For example, you can’t update a purchase order if it has been finalized.

- If the purchase order is controlled by change management in Supply Chain Management, a Field Service user can update the purchase order only when the Supply Chain Management approval status is Draft.
- Several columns are managed only by Supply Chain Management and can't be updated in Field Service. To learn which columns can't be updated, review the mapping tables in the product. For the sake of simplicity, most of these columns are set to read-only on Dataverse pages.

  For example, the columns for price information are managed by Supply Chain Management. Supply Chain Management has trade agreements that Field Service can benefit from. Columns such as **Unit price**, **Discount**, and **Net amount** come only from Supply Chain Management. To ensure that the price is synced to Field Service, you should use the **Sync** feature on the **Purchase Order** and **Purchase Order Product** pages in Dataverse when purchase order data has been entered. For more information, see **Sync with the Dynamics 365 Supply Chain Management procurement data on demand**.

- The **Totals** column is available only in Field Service, because there are no up-to-date totals of the purchase order in Supply Chain Management. The totals in Supply Chain Management are calculated based on multiple parameters that aren't available in Field Service.

- Purchase order lines where only a procurement category is specified, or where the product that is specified is an item of the **Service** product type or Field Service product type, can be initiated only in Supply Chain Management. The lines are then synced to Dataverse and are visible in Field Service.

- If only Field Service is installed, not Supply Chain Management, the **Warehouse** column is mandatory on the purchase order. However, if Supply Chain Management is installed, this requirement is relaxed, because Supply Chain Management allows for purchase order lines where no warehouse is specified in certain situations.

- Product receipts (purchase order receipts in Dataverse) are managed by Supply Chain Management and can't be created from Dataverse if Supply Chain Management is installed. The product receipts from Supply Chain Management are synced from Supply Chain Management to Dataverse.

- Under-delivery is allowed in Supply Chain Management. The OneFSSCM solution adds logic so that, when the product receipt line (or purchase order receipt product in Dataverse) is created or updated, an inventory journal row is created in Dataverse to adjust the remaining quantity that is on order for under-delivery scenarios.

**Unsupported scenarios**

- Field Service prevents lines from being added to a canceled purchase order in Supply Chain Management. As a workaround, you can change the system status of the purchase order in Field Service, and then add the new line in either Field Service or Supply Chain Management.

- Although procurement rows affect inventory levels in both systems, this integration doesn't ensure inventory alignment across Supply Chain Management and Field Service. Both Field Service and Supply Chain Management have other processes that update inventory levels. Those processes are outside the scope of procurement.

**Status management**

The statuses of purchase orders in Field Service differ from the statuses in Supply Chain Management.

**Field Service purchase order and purchase order product statuses**
Supply Chain Management purchase order and purchase order line statuses

Line approval statuses are active only when there is a line workflow.

The following rules are applied to the status columns:

- The status in Supply Chain Management can't be updated from Field Service. However, in some cases, the status in Field Service will be updated when the purchase order status in Supply Chain Management is changed.
- If a purchase order in Supply Chain Management is under change management, and a change is being processed, the approval status is Draft or In Review. In this case, the Field Service approval status will be set to Null.
- If the purchase order approval status in Supply Chain Management is set to Approved, In External review, Confirmed, or Finalized, the Field Service purchase order approval status will be set to Approved.
- If the purchase order approval status in Supply Chain Management is set to Rejected, the Field Service purchase order approval status will be set to Rejected.
- If the document header status in Supply Chain Management is changed to Open order (Back order), and the Field Service purchase order status is Draft or Cancelled, the Field Service purchase order status will be changed to Submitted.
- If the document header status in Supply Chain Management is changed to Cancelled, and no purchase order receipt products in Field Service are associated with the purchase order (via purchase order products), the Field Service system status is set to Cancelled.
- If purchase order line status in Supply Chain Management is Cancelled, the purchase order product status in Field Service is set to Cancelled. In addition, if the purchase order line status in Supply Chain Management is changed from Cancelled to Back Order, the purchase order product item status in Field Service is set to Pending.

Sync with the Supply Chain Management procurement data on demand

Supply Chain Management includes procurement data that handles trade agreements, discounts, and other scenarios that rely on secondary processes in Supply Chain Management. The procurement engine uses complex rules to determine the best price for a given purchase order. When you use dual-write, data isn't always kept synchronous across the two environments, especially in scenarios where the row was created or updated.
Sync the procurement data from Supply Chain Management

1. In Dataverse, go to Inventory > Purchase Order.
2. Select New to create a new purchase order, or select the row for an existing purchase order.
3. From the purchase order or purchase order line.
4. On the Action Pane, select Sync.

All columns from Dataverse and Field Service that are shared by Supply Chain Management are synced.

Here are the situations where you might use the Sync function:

- If you make multiple successive changes to the same row from Dataverse, run the Sync function.
- If you aren’t sure whether a change might be the second successive change from Dataverse, it might make sense to run the Sync function.
- If you receive an error message about updating a value from Supply Chain Management, run the Sync function, and then retry the update in Dataverse.

Cancelling the posting process

If the product receipt posting process is cancelled during processing, then dual-write might create a product receipt row in Dataverse, but not create a product receipt row in Supply Chain Management. This situation happens because dual-write does not support distributed transactions.

Templates

The following templates are available for the integration of procurement-related documents.

<table>
<thead>
<tr>
<th>SUPPLY CHAIN MANAGEMENT</th>
<th>FIELD SERVICE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Purchase order header V2</td>
<td>msdyn_Purchaseorders</td>
<td>This table contains the columns that represent the purchase order header.</td>
</tr>
<tr>
<td>Purchase order line entity</td>
<td>msdyn_PurchaseOrderProducts</td>
<td>This table contains the rows that represent lines on a purchase order. The product number is used for synchronization. This identifies the product as a stock keeping unit (SKU), including product dimensions. For more information about product integration with Dataverse, see Unified product experience.</td>
</tr>
<tr>
<td>Product receipt header</td>
<td>msdyn_purchaseorderreceipts</td>
<td>This table contains the product receipt headers that are created when a product receipt is posted in Supply Chain Management.</td>
</tr>
<tr>
<td>Product receipt line</td>
<td>msdyn_purchaseorderreceiptproducts</td>
<td>This table contains the product receipt lines that are created when a product receipt is posted in Supply Chain Management.</td>
</tr>
<tr>
<td>SUPPLY CHAIN MANAGEMENT</td>
<td>FIELD SERVICE</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Purchase order line soft deleted entity</td>
<td>msdyn_purchaseorderproducts</td>
<td>This table contains information about purchase order lines that are soft-deleted. A purchase order line in Supply Chain Management can be soft-deleted only when the purchase order has been confirmed or approved, if change management is turned on. The row exists in the Supply Chain Management database and is marked as <code>IsDeleted</code>. Because Dataverse doesn't have a concept of soft-deletion, it's important that this information be synced to Dataverse. In this way, lines that are soft-deleted in Supply Chain Management can automatically be deleted from Dataverse. In this case, the logic for deleting a line in Dataverse is located in Supply Chain Management Extended.</td>
</tr>
</tbody>
</table>
Microsoft Dynamics 365 Supply Chain Management includes a pricing engine that handles trade agreements, price lists, customer loyalty programs, promotions, and discounts. The pricing engine uses complex rules to determine the best price for a given quotation or order. When you use dual-write, you use either static pricing or the pricing engine from Dynamics 365 Supply Chain Management on the Quote and Order pages in Dynamics 365 Sales.

**Use the pricing engine from Supply Chain Management in Sales**

1. In Sales, go to **Sales > Orders**.
2. Select **New** to create a new order, or select an existing order in the **My Orders** list.
3. Add a new order line.
4. If you’re creating a new order, select **Price Order** on the Action Pane. If you’re updating an existing order, select **Recalculate** on the Action Pane.

   The following columns are automatically filled in:
   - Detail Amount
   - Discount %
   - Discount
   - Pre-Freight Amount
   - Freight Amount
   - Total Tax
   - Total Amount

5. To ensure that the system considers trade agreements to calculate the price:
   a. Navigate to your Supply Chain Management environment.
   b. Navigate to **Accounts receivable > Setup > Accounts receivable parameters**.
   c. Select the **Prices** tab in the side navigation bar.
   d. Under the **Trade agreement evaluation** fastab, uncheck the **Manual entry** option.

**How it works**

When you select **Price Order** in Sales, the **Totals** function on the **Sales Order > View** tab in Supply Chain Management is called for the associated sales order. The values in the order total in Sales are used to fill in the corresponding columns in Supply Chain Management.

When the sales order total is calculated in Supply Chain Management, the calculation evaluates the existing trade agreements for the customer and the products that are listed in the sales order. This information is used to calculate the totals. When **Price Order** is selected, Sales automatically reflects all the setup that has been done in Supply Chain Management.

**Limitations**
When the columns in Sales are filled in, the following limitations apply:

- The setup of charges and charge allocations in Supply Chain Management isn’t replicated in Sales.
- Pricing doesn’t consider special retail pricing that is specified in the Retail Channel column on the sales order line page in Supply Chain Management.
- Discounts that are defined in the Trade Allowance Management section of Supply Chain Management aren’t considered.
- Pricing doesn’t consider sales agreements.
An important goal of most businesses is to convert prospects to customers and then maintain an ongoing business relationship with those customers. In Microsoft Dynamics 365 apps, the prospect-to-cash process occurs through quotations or order processing workflows, and the financials are reconciled and recognized. Integration of prospect-to-cash with dual-write creates a workflow that takes a quotation and an order that originate in either Dynamics 365 Sales or Dynamics 365 Supply Chain Management, and makes the quotation and order available in both apps.

In the app interfaces, you can access the processing statuses and invoice information in real time. Therefore, you can more easily manage functions such as product stocking, inventory handling, and fulfillment in Supply Chain Management, without having to re-create the quotations and orders.

For information about customer and contact integration, see Integrated customer master. For information about product integration, see Unified product experience.

**NOTE**

In Dynamics 365 Sales, both prospect and customer refer to a record in the Account table where the RelationshipType column is either Prospect or Customer. If your business logic includes an Account qualification process where the Account record is created and qualified as a prospect first and then as a customer, that record synchronizes to the Finance and Operations app only when it is a customer (RelationshipType=Customer). If you want the Account row to synchronize as a prospect, then you need a custom map to integrate the prospect data.

Prerequisites and mapping setup

Before you can sync sales quotations, you must update the following settings.

**Setup in Sales**

In Sales, go to Settings > Administration > System settings > Sales, and make sure that the following settings are used:

- The Use system pricing calculation system option is set to Yes.
- The Discount calculation method column is set to Line item.

**Sites and warehouses**

In Supply Chain Management, the Site and warehouse columns are required for quotation lines and order lines. If you set the site and warehouse in the default order settings, those columns will automatically be set when you add a product to a quotation line or an order line.

**Number sequences for quotations and orders**

The number sequences for Supply Chain Management and Sales aren't connected when quotations and orders are created and synced in Sales and Supply Chain Management. If a sales order that is created in Sales is synced to Supply Chain Management, it has the same sales order number in Supply Chain Management. To help ensure that the sales order number isn't duplicated, you must use different number sequence systems in the two apps.

For example, the number sequence in Supply Chain Management is 1, 2, 3, 4, 5, ..., and the number sequence in Sales is 100, 99, 98, .... If you create 100 sales orders in Sales, an order number will eventually be generated
that already exists in Supply Chain Management. In other words, the two number sequences will eventually overlap as sales orders are created in Supply Chain Management and Sales. Instead, you might use a number sequence such as F1, F2, F3, ... in Supply Chain Management and a number sequence such as C1, C2, C3, ... in Sales. These number sequences will never produce duplicate sales order numbers.

Sales quotations

Sales quotations can be created in either Sales or Supply Chain Management. If you create a quotation in Sales, it’s synced to Supply Chain Management in real time. Likewise, if you create a quotation in Supply Chain Management, it’s synced to Sales in real time. Note the following points:

- You can add a discount to the product on the quotation. In this case, the discount will be synced to Supply Chain Management. The Discount, Charges, and Tax columns on the header are controlled by a setup in Supply Chain Management. This setup doesn’t support integration mapping. Instead, the Price, Discount, Charge, and Tax columns are maintained and handled in Supply Chain Management.
- The Discount %, Discount, and Freight Amount columns on the sales quotation header are read-only columns.
- The Freight terms, Delivery terms, Shipping method, and Delivery mode columns aren't part of the default mappings. To map these columns, you must set up a value mapping that is specific to the data in the organizations that the table is synced between.

If you are also using the Field Service solution, make sure to re-enable the Quote Line Quick Create parameter. Re-enabling the parameter lets you continue creating quote lines using the quick create function.

1. Navigate to your Dynamics 365 Sales application.
2. Select the settings icon in the top navigation bar.
3. Select Advanced Settings.
4. Choose the Customize the System option.
5. Select the Quote Line menu item.
6. Go to the Data Services section and select the Allow quick create checkbox.

Sales orders

Sales orders can be created in either Sales or Supply Chain Management. If you create a sales order in Sales, it’s synced to Supply Chain Management in real time. Likewise, if you create a sales order in Supply Chain Management, it’s synced to Sales in real time. Note the following points:

- Write-in products on Dynamics 365 Sales will appear as product categories in Dynamics 365 Supply Chain Management.
- Discount calculation and rounding:
  - The discount calculation model in Sales differs from the discount calculation model in Supply Chain Management. In Supply Chain Management, the final discount amount on a sales line can be the result of a combination of discount amounts and discount percentages. If this final discount amount is divided by the quantity on the line, rounding can occur. However, this rounding isn’t considered if a rounded per-unit discount amount is synced to Sales. To help ensure that the full discount amount from a sales line in Supply Chain Management is correctly synced to Sales, the full amount must be synced without being divided by the line quantity. Therefore, you must define the discount calculation method as Line item in Sales.
  - When a sales order line is synced from Sales to Supply Chain Management, the full line discount amount is used. Because Supply Chain Management has no column that can store the full discount amount for a line, the amount is divided by the quantity and stored in the Line discount column. Any rounding that occurs during this division is stored in the Sales charges column on the sales line.
Example: Synchronization from Sales to Supply Chain Management

You have the following sales order:

- **Sales**: Quantity = 3, per-line discount = $10.00
- **Supply Chain Management**: Quantity = 3, line discount amount = $3.33, sales charge = –$0.01

If you sync from Supply Chain Management to Sales, you get the following result:

- **Supply Chain Management**: Quantity = 3, line discount amount = $3.33, sales charge = –$0.01
- **Sales**: Quantity = 3, per-line discount = (3 × $3.33) + $0.01 = $10.00

Dual-write solution for Sales

New columns have been added to the **Order** table and appear on the page. Most of these columns appear on the **Integration** tab in Sales. To learn more about how the status columns are mapped, see [Set up the mapping for sales order status columns](#).

- The **Create Invoice** and **Cancel Order** buttons on the **Sales order** page are hidden in Sales.
- The **Sales order status** value will remain **Active** to help ensure that changes from Supply Chain Management can flow to the sales order in Sales. To control this behavior, set the default **Statecode [Status]** value to **Active**.

Invoices

Sales invoices are created in Supply Chain Management and synced to Sales. Note the following points:

- An **Invoice number** column has been added to the **Invoice** table and appears on the page.
- The **Create invoice** button on the **Sales order** page is hidden, because invoices will be created in Supply Chain Management and synced to Sales. The **Invoice** page can’t be edited, because invoices will be synced from Supply Chain Management.
- The **Sales order status** value is automatically changed to **Invoiced** when the related invoice from Supply Chain Management has been synced to Sales. Additionally, the owner of the sales order that the invoice was created from is assigned as the owner of the invoice. Therefore, the owner of the sales order can view the invoice.
- The **Freight terms**, **Delivery terms**, and **Delivery mode** columns aren’t included in the default mappings. To map these columns, you must set up a value mapping that is specific to the data in the organizations that the table is synced between.

Templates

Prospect-to-cash includes a collection of core table maps that work together during data interaction, as shown in the following table.

<table>
<thead>
<tr>
<th>FINANCE AND OPERATIONS APPS</th>
<th>CUSTOMER ENGAGEMENT APPS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>All products</td>
<td>msdyn_globalproducts</td>
<td></td>
</tr>
<tr>
<td>Customers V3</td>
<td>accounts</td>
<td></td>
</tr>
<tr>
<td>Customers V3</td>
<td>contacts</td>
<td></td>
</tr>
<tr>
<td>Contacts V2</td>
<td>msdyn_contactforparties</td>
<td></td>
</tr>
<tr>
<td>CDS sales order headers</td>
<td>salesorders</td>
<td></td>
</tr>
</tbody>
</table>
For information about price lists, see [Unified product experience](#).

**Limitations**

- Return orders are not supported.
- Credit notes are not supported.
- Financial dimensions must be set for the master data, for example, customer and vendor. When a customer is added to a quotation or sales order, the financial dimensions associated with the customer record flow to the order automatically. Currently dual-write does not include financial dimensions data for master data.
This topic describes how to use the Microsoft Dynamics 365 Commerce pricing engine to create sales quotations in Dynamics 365 Sales.

The Dynamics 365 Commerce pricing engine supports most business-to-consumer (B2C) pricing scenarios, such as store-level pricing, affiliation-based and loyalty-based pricing, mix-and-match discounts, quantity discounts, and threshold discounts. The pricing engine uses complex rules to determine the best price for a given quotation or order.

When you use dual-write, you have three options for your pricing needs. You can use the static pricing that comes from the price list in Dynamics 365 Sales, the pricing engine in Dynamics 365 Supply Chain Management, or the pricing engine in Dynamics 365 Commerce. Among these options, the Commerce pricing engine is best suited to B2C scenarios.

**Use the Commerce pricing engine in Sales**

**NOTE**

Currently, the Commerce pricing engine can be used only for quotation creation in the Sales. Sales order integration with the Commerce pricing engine isn't yet available.

When users initiate a quotation in Sales, the dual-write framework copies the quotation details to Commerce. Any changes to existing quotation lines or any newly added quotation lines in Sales are copied to Commerce. When users want to use the Commerce pricing engine to price the quotation, they can select **Price quote** to update the prices of the quotation, based on the Commerce pricing engine. Prices are then automatically updated in both Sales and Commerce.

**Prerequisites**

- Before you can use the Commerce pricing engine in Sales, you must follow the steps in Prospect-to-cash in dual-write.
- You must turn off trade agreement evaluation for manual entry by following these steps:
  1. In your Commerce environment, go to Accounts receivable > Setup > Accounts receivable parameters.
  2. On the Prices tab, on the Trade agreement evaluation FastTab, clear the Manual entry check box.

**Additional resources**

Prospect-to-cash in dual-write
Microsoft Dynamics 365 Field Service is designed to service customer assets. Asset management for Dynamics 365 Supply Chain Management is designed to maintain in-house assets. Integration of these two apps lets you use Field Service to service both customer assets and in-house assets. You can also classify the assets, based on functional location or hierarchy, and track the servicing at a detailed level.

For more information, see [Integrate Dynamics 365 Field Service and Supply Chain Management](#).

### Templates

In-house assets include a collection of core table maps that work together during data interaction, as shown in the following table.

<table>
<thead>
<tr>
<th>FINANCE AND OPERATIONS APPS</th>
<th>CUSTOMER ENGAGEMENT APPS</th>
<th>DESCRIPTION</th>
</tr>
</thead>

</table>
By using inventory availability, you can check your inventory before you add a product to the Quotations, Orders, or Invoices page in Microsoft Dynamics 365 Sales. For example, you check inventory and determine a fulfillment date as one key task in the prospect-to-cash process.

If you don't have enough inventory, you can estimate a delivery date, based on projected inventory receipts and issues. You can also check the product's available-to-promise (ATP) information, where you can find the ATP quantity in the predefined time fence.

**On-hand inventory**

In Dynamics 365 Sales, a new **On-hand Inventory** button has been added to the header of the Quotes, Orders, and Invoices pages. When you select this button, a dialog box appears, where you can specify the company and the product that you want to check the on-hand inventory for. This dialog box shows the same information as **On-hand inventory**.

The dialog box returns the inventory information from Dynamics 365 Supply Chain Management. This information includes the following quantities:

- On-hand quantity
- Reserved on-hand quantity
- Available on-hand quantity
- Ordered quantity
- On-order quantity
- Reserved ordered quantity
- Total available quantity

**ATP information**

In Sales, a new **ATP Information** button has been added to line items on the Quotes, Orders, and Invoices pages. When you select this button, a dialog box appears, where you can specify the company, product, inventory site, inventory warehouse, and order quantity. This dialog box has the same settings that are described in **Order promising**.

The dialog box returns the ATP information from Supply Chain Management. This information includes the following quantities:

- ATP quantity
- Receipt quantity
- Issue quantity
- On-hand quantity

**How it works**

When you select the **On-hand Inventory** button on the Quotes, Orders, or Invoices page, a live dual-write call is made to the **Onhand inventory** API. The API calculates the on-hand inventory for the given product. The result is stored in the **InventCDSInventoryOnHandRequestEntity** and **InventCDSInventoryOnHandEntryEntity** tables, and then is written to Dataverse by dual-write. To use this
Functionality, you need to run the following dual-write maps. Skip initial synchronization when you run the maps.

- CDS inventory on-hand entries (msdyn_inventoryonhandentries)
- CDS inventory on-hand requests (msdyn_inventoryonhandrequests)

## Templates

The following templates are available for the exposing the onhand inventory data.

<table>
<thead>
<tr>

<th>CUSTOMER ENGAGEMENT APPS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDS inventory on-hand entries</td>
<td>msdyn_inventoryonhandentries</td>
<td></td>
</tr>
<tr>
<td>CDS inventory on-hand requests</td>
<td>msdyn_inventoryonhandrequests</td>
<td></td>
</tr>
</tbody>
</table>
While mastered in only one app, worker data can be synchronized across multiple Dynamics 365 apps. For example, human resources (HR) data can be mastered in Dynamics 365 Human Resources and synchronized with Dynamics 365 Commerce, Dynamics 365 Finance, and Dynamics 365 Supply Chain Management. The data is integrated seamlessly behind the scenes. The ability to integrate data about workers ensures you're working with the same data across all Dynamics 365 apps, providing you a comprehensive view of your information.

Human resources

The integration of HR data involves just mapping the HR data between finance and operations apps and customer engagement apps.

Templates

HR data includes information about employees and contractors, positions, and jobs. A collection of table maps works together during data interaction, as shown in the following table.

<table>
<thead>
<tr>
<th>FINANCE AND OPERATIONS APPS</th>
<th>CUSTOMER ENGAGEMENT APPS</th>
<th>DESCRIPTION</th>
</tr>

</tr>
</tbody>
</table>
Party and global address book are concepts in Finance and Operations applications. A party can be an organization or a person. It's convenient to globally store and manage properties of a party, such as the name, language, contacts, and addresses. Then, when a property value is changed in one place, the change is reflected in all places where the party is involved.

Party

A party is a person or an organization that is involved in a business. When the party concept is used, a person or an organization can play more than one role in a business (for example, worker, customer, vendor, or contact). The role is based on the context and purpose. Here are some examples of roles from two fictitious companies, Contoso and Fabrikam:

- **Worker** – An employee. An example is an employee of Contoso.
- **Vendor** – A supplier organization, or a sole proprietor who supplies goods or services to a business. For example, if Fabrikam sells supplies to Contoso, Fabrikam is a vendor of Contoso.
- **Contact** – A person to contact. For example, if Contoso buys supplies from Fabrikam, employees at Contoso will reach out to the contact at Fabrikam.
- **Customer** – A person or company that buys things from a company. For example, if Contoso buys supplies from Fabrikam, Contoso is a customer of Fabrikam.

The party model is often used to represent medium to complex relationships between organizations and people, especially when a party plays more than one role. Here are some common examples:

- A party can be both a customer and a vendor. For example, in North America, Fabrikam sells electric wires to Contoso and buys assembled speakers from Contoso. In Europe, Fabrikam sells parts to Contoso, but it doesn't buy anything from Contoso.
- A party can be both an employee and a customer. For example, an employee of Contoso buys electronics from Contoso for personal use.
- There can be a many-to-many (N:N) relationship between a person and an organization. For example, Fabrikam provides service specialists and employs a placement coordinator. The placement coordinator matches service specialists to work requests from several of Fabrikam’s customers. Contoso is one of Fabrikam's customers. When Contoso requires a service specialist, it contacts the placement coordinator, who then facilitates the request. Because the placement coordinator handles requests for all customers, an N:N relationship is involved.

The following illustration shows the data model for party.
TIP

When you’re trying to create a new account record, use the **Party** field to search for the record by name. In this way, if you find the record, you just have to select it. The system then automatically fills in all the data from the party. You don’t have to manually set all the required fields. This behavior can be found on the out-of-box **Account**, **Contact**, and **Vendor** pages.

Dual-write doesn’t support all party roles of Finance and Operations apps. For a complete list of party roles, see Global address book overview.

Global address book

The global address book is a directory of postal and electronic addresses of the organizations and individuals that participate in a business.

The global address book stores and handles as many postal addresses and electronic addresses as required. For example, Fabrikam has gas stations in 50 locations. Each location has a different postal address, email address, and phone number. All business purchases are billed to the main gas station but shipped directly to the specific gas station that requested the purchase. The global address book stores the main gas station as the billing address for Fabrikam and stores each gas station as a shipping address. The addresses can be stored one time...
and then retrieved as they are required for quotations and orders.

Depending on the business context, a person or an organization might play more than one role, and the same postal address and electronic address might be used for all the roles. In this case, a change of address in one role should appear in all the other roles. The global address book stores and handles addresses globally.

The following illustration shows the data model for the global address book.

**Contact**

In customer engagement apps, a contact is a person. However, the Contact table has been overloaded to represent a person, a portal user, a business-to-consumer (B2C) customer, or a vendor. The representation is implicit, and you can’t tell the difference unless you examine related transactions. The Contact table has been limited to a one-to-one (1:1) relationship with the Account table. As part of the party and global address book model, dual-write introduces explicit properties for classification and allows for N:N relationships between a contact that is a person and an organization (Account or Vendor entity).

There are two types of Contact rows:

- **Striped contact** – A Contact row where the Company field has a mandatory value.
- **Unstriped contact** – A Contact row where the Company field is blank.

The Contact table can store the following types of rows.

<table>
<thead>
<tr>
<th>ROW TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>A person who is a customer (for example, a sellable contact or a B2C customer)</td>
<td>A striped contact record where the Company field isn’t blank and the Is Customer field is set to Yes.</td>
</tr>
<tr>
<td>A person who is a vendor (for example, a sole proprietor such as a vendor)</td>
<td>A striped contact record where the Company field isn’t blank and the Is Vendor field is set to Yes.</td>
</tr>
</tbody>
</table>
Contact for Party table

The Contact for Party table stores and handles N:N relationships between Account rows and Contact rows. It can filter out the striped Contact rows from unstriped rows and associate only the unstriped Contact rows with Account or Vendor rows.

For example, Natasha Jones and Miguel Reyes are veterinarians who provide care for farms in their areas. Natasha serves the Seattle area, and Miguel serves the Kent area. In the customer engagement app, the farms are represented as customers, and the veterinarians are represented as contact persons. A single Contact record for Natasha is associated with all the farms that Natasha works with. Likewise, a single Contact record for Miguel is associated with all the farms that Miguel works with.

These relationships are stored in the Contact for Party table. You can find the information on the out-of-box Account, Contact, and Vendor pages:

- On the Account page, you can use the Associated Contacts tab to associate one or more contacts with the Account row. In this way, you assign contact persons for an organization. You can then select one contact as the primary contact for the account. If you use the Quick create page, you can only select a contact person. The behavior is the same when you're using the Vendor page and the record type is Organization.

- On the Contact page, when the row is a customer, a vendor, or both (a striped contact), you can use the Associated Contacts tab to associate one or more contacts. In this way, you assign contact persons for a B2C customer or vendor. You can then select one contact as the primary contact. If you use the Quick create page, you can only select a contact person.

- On the Contact page, when the row is a contact person (an unstriped contact), you can use the Associated Organizations tab to associate one or more customers or vendors. In this way, you assign customers or vendors to the underlying contact person. The customer or vendor can be an organization, a person, or both. You can select a value in only one of the four fields at a time:
  - If you select a value in the Party ID field, the underlying contact is assigned to all the roles of the selected party.
  - If you select a value in the Associated Contact field, you're selecting the striped contact of the Person type.
  - If you select a value in the Associated Account or Associated Vendor field, you're selecting an organization.

<table>
<thead>
<tr>
<th>ROW TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>A person who is both a customer and a vendor</td>
<td>An striped contact record where the Company field isn't blank, the Is Customer field is set to Yes, and the Is Vendor field is set to Yes. A person can be both a producer for one product and a consumer for another product. Both Finance and Operations apps and dual-write support this relationship.</td>
</tr>
<tr>
<td>A person who is a contact person for an organization, but isn't a customer or a vendor</td>
<td>An unstriped contact record where the Company field is blank, the Is Customer field is set to No, and the Is Vendor field is set to No.</td>
</tr>
</tbody>
</table>
Regardless of your selection, the association is created at the party level, it applies to all the roles of the party, and it’s stored in the **Contact for Party** entity.

**NOTE**

The display name for the **Contact for Party** table in customer engagement apps is **Contact for Customer/Vendor**.

When you open a **Contact** row where both the **Is Customer** field and the **Is Vendor** are set to **No**, the **Associated Organizations** tab is shown. Use this tab to associate one or more customer or vendor organizations with the contact.

When you open a **Contact** row where either the **Is Customer** field or the **Is Vendor** field is set to **Yes**, the **Associated Contacts** tab is shown. Use this tab to associate one or more contacts.

### Postal addresses

A new **Addresses** tab has been introduced on the **Account**, **Contact**, and **Vendor** pages. This tab supports multiple postal addresses by using a grid, as shown in the following illustration.

The grid includes the following columns:

- **Postal Address Roles** – The purpose of the postal address.
- **Is Primary** – A value that indicates whether the address is the primary address.
- **Address Number** – The address order.

You can use the **New Address** button above the grid to create as many postal addresses as you want.

The **Address 1** and **Address 2** fields on the **Summary** tab of the **Account** page correspond to the **Delivery** and **Invoice** addresses, respectively.
The Address 1, Address 2, and Address 3 fields on the Summary tab of the Contact page correspond to the Business, Delivery, and Invoice addresses, respectively.

Electronic addresses

A new Electronic Addresses tab has been introduced on the Account, Contact, and Vendor pages. This tab supports multiple electronic addresses by using a grid, as shown in the following illustration.

The grid includes the following columns:

- **Type** – The type of electronic address.
- **Is Primary** A value that indicates whether the address is the primary address.
- **Purpose** – The purpose of the electronic address.

You can use the New Electronic Address button above the grid to create as many addresses as you want.

Electronic addresses are available only in this grid. In future releases, all postal address and electronic address fields will be removed from other tabs, for example, the Summary and Details tabs. Contact details displayed on the Details tab are read-only copies of the primary electronic address, like primary phone, primary email, primary telephone, primary fax, and primary Twitter ID. During the lead qualification process you can provide both a business phone number and a mobile phone number. The business phone number is considered the primary phone if IsMobile=No and the mobile phone number is considered the secondary phone if IsMobile=Yes.

<table>
<thead>
<tr>
<th>Tip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Addresses and Electronic Addresses tabs on the Account and Contact forms to manage postal and electronic addresses. This ensures that address data synchronizes to Finance and Operations apps.</td>
</tr>
</tbody>
</table>

Setup

1. Open your customer engagement app environment.
2. Install the latest version (2.2.2.60 or later) of Dual-write application orchestration solution.
3. Install Dual-write Party and Global Address Book Solutions.
4. Open the finance and operations app. Navigate to the Data Management module and select the Dual-write tab. The dual-write administration page opens.
5. Apply both the solutions installed in steps 2 and 3 using the Apply Solution function.
6. Stop the following maps, because they aren’t required anymore. Instead, run the Contacts V2 (msdyn_contactforparties) map.
   - CDS Contacts V2 and Contacts (refers to customer contacts)
   - CDS Contacts V2 and Contacts (refers to vendor contacts)
7. The following entity mappings are updated for party functionality, so the latest version must be applied to these mappings.
<table>
<thead>
<tr>
<th>MAP</th>
<th>UPDATE TO THIS VERSION</th>
<th>CHANGES</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDS Parties (msdyn_parties)</td>
<td>1.0.0.0</td>
<td>This is a new map added as part of this release.</td>
</tr>

msdyn_company.cdm_companycode [Company (Company Code)] |

9. In Dataverse, the duplicate detection rules character limits have increased from 450 to 700 characters. This limit lets you add one or more keys to the duplicate detection rules. Expand the duplicate detection rule for the **Accounts** table by setting the following fields.

<table>
<thead>
<tr>
<th>FIELD</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Accounts with the same account name.</td>
</tr>
<tr>
<td>Description</td>
<td>Detects account records that have the same value in the Account Name attribute.</td>
</tr>
<tr>
<td>Base Record Type</td>
<td>Account</td>
</tr>
<tr>
<td>Matching Record Type</td>
<td>Account</td>
</tr>
<tr>
<td>Account Name (field)</td>
<td>Exact Match</td>
</tr>
</tbody>
</table>
10. Expand the duplicate detection rule for the **Contacts** table by setting the following fields.

<table>
<thead>
<tr>
<th>FIELD</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Contacts with the same first name and last name.</td>
</tr>
<tr>
<td>Description</td>
<td>Detects contact records that have the same values in the First Name and Last Name fields.</td>
</tr>
<tr>
<td>Base Record Type</td>
<td>Contact</td>
</tr>
<tr>
<td>Matching Record Type</td>
<td>Contact</td>
</tr>
<tr>
<td>First Name (field)</td>
<td>Exact Match</td>
</tr>
<tr>
<td>Last Name (field)</td>
<td>Exact Match</td>
</tr>
<tr>
<td>Company (field)</td>
<td>Exact Match</td>
</tr>
<tr>
<td>Party Id (field)</td>
<td>Exact Match</td>
</tr>
<tr>
<td>Select (field)</td>
<td>(blank)</td>
</tr>
</tbody>
</table>
11. If you are an existing dual-write user, follow the instructions in Upgrade to the party and global address book model and upgrade your data.

12. Run the maps in the following order. If you get an error that states "Project validation failed. Missing destination field...", then open the map and select Refresh Tables. Then run the map.

<table>
<thead>
<tr>
<th>FINANCE AND OPERATIONS APP</th>
<th>CUSTOMER ENGAGEMENT APP</th>

</tr>
</tbody>
</table>
The CDS Contacts V2 (contacts) map is the map that you stopped in the step 1. When you try to run other maps, these 2 maps may appear in the list of dependents. Don't run these maps.

If the party and global address book solution is installed, you must disable the plugin named Microsoft.Dynamics.SCMExtended.Plugins.Plugins.LeadPrimaryContactPostCreate: QualifyLead of lead. If you uninstall the party and global address book solution, then you must re-enable the plugin.

The msdyn_*partynumber field (a single line text field) that is included in the Account, Contact and Vendor tables should not be used going forward. The label name has a prefix of (Deprecated) for clarity. Instead, use the msdyn_partyid field. The field is a lookup to the msdyn_party table.

<table>
<thead>
<tr>
<th>TABLE NAME</th>
<th>OLD FIELD</th>
<th>NEW FIELD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account</td>
<td>msdyn_partynumber</td>
<td>msdyn_partyid</td>

### Known issues and limitations

- In Finance and Operations apps, when you create a customer along with address and save it, the address might not synchronize to the **Address** table. This is because of a dual-write platform sequencing issue. As a workaround, create the customer first and save it. Then add the address.

- In Finance and Operations apps, when a customer record has a primary address and you create a new contact for that customer, then the contact record inherits a primary address from the associated customer record. This happens for vendor contact, too. Dataverse doesn’t currently support this behavior. If dual-write is enabled, a customer contacts that is inherited with a primary address from the Finance and Operations app is synchronized to Dataverse along with its address.

- Electronic addresses set on the electronic address tab of the **Account**, **Contact**, and **Vendor** forms come from the **msdyn_partyelectronicaddresses** table. This information does not flow to its associated transactions like sales order, quotation, and purchase order. We plan to fix this issue in an incremental release. The existing data on the electronic address fields on the account and contact records will continue to work on transactions like sales order, quotation, and purchase order.

- In Finance and Operations apps, you can create a contact record from the **Add Contact** form. When you try to create a new contact from the **View Contact** form, the action fails. This is a known issue.
Initial sync does not support the Available From and Available To time fields on ContactForParty, because DIXF converts the value into a string instead of an integer. The conversion triggers the error "Cannot convert the literal '<say 08:00:00>' to the expected type edm.int32."

When a postal address is used for more than one reason, for example, business communication address and billing address, it should appear as Business;Invoice as shown in the following image. If you add a space in between the values, you will get an error.

You can’t enter a forward-dated postal address using a Finance and Operations app with dual-write, because Dataverse does not support date effectivity. If you enter a future-dated postal address using a Finance and Operations app, it synchronizes to Dataverse fully and you will see the address on the user interface immediately. Any updates to this record will result in an error as it is future-dated and not current in the Finance and Operations app.
The Dual-write application orchestration solution version 2.0.999.0 and later includes data model changes to party and global address book for the Account and Contact tables. The changes allow many-to-many relationships that support advanced business scenarios. These changes are not supported by portal web roles, including the customer portal, that are shipped out-of-the-box or that existed in your environment before you installed dual-write. For the web roles to work as expected, you need to create new web roles by using the new data model.

In summary, the way the tables interact has changed, but the table permissions in the customer portal haven’t changed. This topic explains how to create new web roles that work with the new advanced data model.

This diagram shows the table relationship without the party and global address book data model:

```
Account -> Contacts
```

This diagram shows the table relationship with the party and global address book data model:
Create a new table permission

To create these new table permissions, follow these steps:

1. Sign in to Power Apps, and go to your apps.
2. Select your Portal Management app.
3. In the side bar, select Security > Table permissions.

You must create three new permissions:

- Contact to Party table connection
- Party to Account table connection
- Account to Order table connection

4. Create and save a new permission for the Contact to Party connection, setting these parameters:
   - **Name**: Party to Account table connection (or your choice)
   - **Table Name**: msdyn_contactforparty
5. Create and save a new permission for the Party to Account connection, setting these parameters:

- **Name**: Party to Account Connection (or your choice)
- **Table Name**: account
- **Website**: Customer Portal
- **Scope**: Parent
- **Privileges**: Select all
- **Parent Table Permission**: Contact to Party Connection

6. Create and save a new permission for the Account to Order connection, setting these parameters:

- **Name**: Account to Order Connection (or your choice)
- **Table Name**: salesorder
- **Website**: Customer Portal
- **Scope**: Parent
- **Privileges**: Select all
- **Parent Table Permission**: Party to Account Connection
The Microsoft Azure Data Factory templates help you upgrade the following existing data in dual-write to the party and global address book model: data in the **Account**, **Contact**, and **Vendor** tables, and postal and electronic addresses.

The following three Data Factory templates are provided. They help reconcile the data from both Finance and Operations apps and customer engagement apps.

- **Party template** *(Upgrade data to dual-write Party-GAB schema/arm_template.json)* – This template helps upgrade **Party** and **Contact** data that is associated with **Account**, **Contact**, and **Vendor** data.

- **Party postal address template** *(Upgrade data to dual-write Party-GAB schema/Upgrade to Party Postal Address - GAB/arm_template.json)* – This template helps upgrade the postal addresses that are associated with **Account**, **Contact**, and **Vendor** data.

- **Party electronic address template** *(Upgrade data to dual-write Party-GAB schema/Upgrade to Party Electronic Address - GAB/arm_template.json)* – This template helps upgrade electronic addresses that are associated with **Account**, **Contact**, and **Vendor** data.

At the end of the process, the following comma-separated values (.csv) files are generated.

<table>
<thead>
<tr>
<th>FILE NAME</th>
<th>PURPOSE</th>
</tr>
</thead>
<tbody>
<tr>
<td>FONewParty.csv</td>
<td>This file helps create new <strong>Party</strong> records inside the Finance and Operations app.</td>
</tr>
<tr>
<td>ImportFONewPostalAddressLocation.csv</td>
<td>This file helps create new <strong>Postal Address Location</strong> records in the Finance and Operations app.</td>
</tr>
<tr>
<td>ImportFONewPartyPostalAddress.csv</td>
<td>This file helps create new <strong>Party Postal address</strong> records in the Finance and Operations app.</td>
</tr>
<tr>
<td>ImportFONewPostalAddress.csv</td>
<td>This file helps create new <strong>Postal Address</strong> records in the Finance and Operations app.</td>
</tr>
<tr>
<td>ImportFONewElectronicAddress.csv</td>
<td>This file helps create new <strong>Electronic Address</strong> records in the Finance and Operations app.</td>
</tr>
</tbody>
</table>

This topic explains how to use the Data Factory templates and upgrade your data. If you don’t have any customizations, you can use the templates as they are. However, if you have customizations for **Account**, **Contact**, and **Vendor** data, you must modify the templates as described in this topic.

**IMPORTANT**

There are special instructions if you will run the Party postal address and Party electronic address templates. You must run the Party template first, then the Party postal address template, and then the Party electronic address template.
Prerequisites

The following prerequisites must be in place before you can upgrade to the party and global address book model:

- You must have an Azure subscription.
- You must have access to the templates.
- You must be an existing dual-write customer.

Prepare for the upgrade

An upgrade requires the following preparation:

- **Full synchronization**: Both the Finance and operations environment and the customer engagement environment are in a fully synced state for the Account (Customer), Contact, and Vendor tables.
- **Integration keys**: The Account (Customer), Contact, and Vendor tables in customer engagement apps are using the out-of-box integration keys. If you customized the integration keys, you must customize the template.
- **Party number**: All Account (Customer), Contact, and Vendor records that will be upgraded have a party number. Records that don't have a party number will be ignored. If you want to upgrade those records, add a party number to them before you start the upgrade process.
- **System outage**: During the upgrade process, you will have to take both the Finance and operations environment and the customer engagement environment offline.
- **Snapshot**: Take a snapshot of both the Finance and Operations apps and the customer engagement apps. You can then use the snapshots to restore the previous state if you must.

Deployment

1. Download the templates from Dynamics-365-FastTrack-Implementation-Assets.
2. Sign in to the Azure portal.
3. Create a resource group.
4. Create a storage account in the resource group that you created.
5. Create a data factory in the resource group that you created.
6. Open the data factory, and select the Author & Monitor tile.
7. On the Manage tab, select ARM template.
8. Select Import ARM template to import the Party template.
9. Import the template into the data factory. Enter the following values for Project details and Instance details.

<table>
<thead>
<tr>
<th>FIELD</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subscription</td>
<td>The Azure subscription</td>
</tr>
<tr>
<td>Resource group</td>
<td>Provide the same resource that the storage account is created under</td>
</tr>
<tr>
<td>Region</td>
<td>The region</td>
</tr>
<tr>
<td>FIELD</td>
<td>VALUE</td>
</tr>
<tr>
<td>--------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Factory Name</td>
<td>The factory name</td>
</tr>
<tr>
<td>FO Linked Service_service Principal Key</td>
<td>The application's key</td>
</tr>
<tr>
<td>Azure Blob Storage_connection String</td>
<td>The Azure Blob storage connection string</td>
</tr>
<tr>
<td>Dynamics Crm Linked Service_password</td>
<td>The password for the user account that you specify as the user name</td>
</tr>
<tr>
<td>FO Linked Service_properties_type Properties_url</td>
<td><a href="https://sampledynamics.sandbox-operationsdynamics.com/data">https://sampledynamics.sandbox-operationsdynamics.com/data</a></td>
</tr>
<tr>
<td>FO Linked Service_properties_type Properties_tenant</td>
<td>Information (domain name or tenant ID) about the tenant that your application resides under</td>
</tr>
<tr>
<td>FO Linked Service_properties_type Properties_aad Resource Id</td>
<td><a href="https://sampledynamics.sandboxoperationsdynamics.com">https://sampledynamics.sandboxoperationsdynamics.com</a></td>
</tr>
<tr>
<td>FO Linked Service_properties_type Properties_service Principal Id</td>
<td>The application's client ID</td>
</tr>
<tr>
<td>Dynamics Crm Linked Service_properties_type Properties_username</td>
<td>The user name that is used to connect to Dynamics 365</td>
</tr>
</tbody>
</table>

For more information, see the following topics:

- [Manually promote a Resource Manager template for each environment](#)
- [Linked service properties](#)
- [Copy data using Azure Data Factory](#)

10. After deployment, validate the datasets, data flow, and linked service of the data factory.

11. Go to Manage. Under Connections, select Linked Service. Then select DynamicsCrmLinkedService. In the Edit linked service (Dynamics CRM) dialog box, enter the following values.

<table>
<thead>
<tr>
<th>FIELD</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>DynamicsCrmLinkedService</td>
</tr>
</tbody>
</table>
Prepare to run the Data Factory templates

This section describes the setup that is required before you run the Party postal address and Party electronic address Data Factory templates.

Setup to run the Party postal address template

1. Sign in to customer engagement apps, and go to Settings > Personalization Settings. Then, on the General tab, configure time zone setting for the system admin account. The time zone must be in Coordinated Universal Time (UTC) to update the “valid from” and “valid to” dates of postal addresses from Finance and Operations apps.

   **Set the time zone you are in**

   ![Time Zone Selector](https://example.com/timezone-selector.png)

2. In Data Factory, on the Manage tab, under Global parameters, create the following global parameter.

<table>
<thead>
<tr>
<th>NUMBER</th>
<th>NAME</th>
<th>TYPE</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>PostalAddressIdPrefix</td>
<td>string</td>
<td>This parameter appends a serial number to newly created postal addresses as a prefix. Be sure to provide a string that doesn't conflict with postal addresses in Finance and Operations apps and customer engagement apps. For example, use <strong>ADF-PAD-</strong>.</td>
</tr>
</tbody>
</table>
3. When you've finished, select **Publish all**.

### Setup to run the Party electronic address template

1. In Data Factory, on the **Manage** tab, under **Global parameters**, create the following global parameters.

<table>
<thead>
<tr>
<th>NUMBER</th>
<th>NAME</th>
<th>TYPE</th>
<th>VALUE</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>IsFOSource</td>
<td>bool</td>
<td></td>
<td>This parameter determines which primary system addresses are replaced in the event of conflicts. If the value is <strong>true</strong>, the primary addresses in Finance and Operations apps will replace the primary addresses in customer engagement apps. If the value is <strong>false</strong>, the primary addresses in customer engagement apps will replace the primary addresses in Finance and Operations apps.</td>
</tr>
<tr>
<td>2</td>
<td>ElectronicAddressIdPrefix</td>
<td>string</td>
<td></td>
<td>This parameter appends a serial number to newly created electronic addresses as a prefix. Be sure to provide a string that doesn't conflict with electronic addresses in Finance and Operations apps and customer engagement apps. For example, use <strong>ADF-EAD-</strong>.</td>
</tr>
</tbody>
</table>

2. When you've finished, select **Publish all**.

### Run the templates

1. Stop the following **Account**, **Contact**, and **Vendor** dual-write maps that use the Finance and Operations
app:

- Customers V3(accounts)
- Customers V3(contacts)
- CDS Contacts V2(contacts)
- CDS Contacts V2(contacts)
- Vendor V2 (msdyn_vendor)

2. Make sure that the maps are removed from the **msdy_dualwriteruntimeconfig** table in Dataverse.

3. Install **Dual-write Party and Global Address Book Solutions** from **AppSource**.

4. In the Finance and Operations app, run **Initial Sync** for the following tables if they contain data:

   - Salutations
   - Personal character types
   - Complimentary closing
   - Contact person titles
   - Decision making roles
   - Loyalty levels

5. In the customer engagement app, disable the following plug-in steps:

   - **Account Update**
     - Microsoft.Dynamics.FinanceExtended.Plugins.TriggerNotesForCustomerTypeCodes: Update of account
   - **Contact Update**
     - Microsoft.Dynamics.GABExtended.Plugins.UpdatePartyAttributesFromContactEntity: Update of contact
     - Microsoft.Dynamics.FinanceExtended.Plugins.TriggerNotesForSellableContact: Update of contact
   - **msdyn_party Update**
   - **msdyn_vendor Update**
   - **Customeraddress**
     - Create
       - Microsoft.Dynamics.GABExtended.Plugins.CreatePartyAddress: Create of customeraddress
     - Update
       - Microsoft.Dynamics.GABExtended.Plugins.CreatePartyAddress: Update of customeraddress
     - Delete
       - Microsoft.Dynamics.GABExtended.Plugins.DeleteCustomerAddress: Delete of customeraddress
- msdyn_partypostaladdress
  - Create
    - Microsoft.Dynamics.GABExtended.Plugins.CreateCustomerAddress: Create of msdyn_partypostaladdress
    - Microsoft.Dynamics.GABExtended.Plugins.PartyPostalAddress: Create of msdyn_partypostaladdress
  - Update
    - Microsoft.Dynamics.GABExtended.Plugins.CreateCustomerAddress: Update of msdyn_partypostaladdress
- msdyn_postaladdress
  - Create
    - Microsoft.Dynamics.GABExtended.Plugins.PostalAddress: Create of msdyn_postaladdress
    - Microsoft.Dynamics.GABExtended.Plugins.PostalAddressPostCreate: Create of msdyn_postaladdress
    - Microsoft.Dynamics.GABExtended.Plugins.UpdateCustomerAddress: Create of msdyn_postaladdress
  - Update
    - Microsoft.Dynamics.GABExtended.Plugins.PostalAddressUpdate: Update of msdyn_postaladdress
    - Microsoft.Dynamics.GABExtended.Plugins.UpdateCustomerAddress: Update of msdyn_postaladdress
- msdyn_partyelectronicaddress
  - Create
    - Microsoft.Dynamics.GABExtended.Plugins.PartyElectronicAddressSync: Create of msdyn_partyelectronicaddress
  - Update
  - Delete

6. In the customer engagement app, disable the following workflows:
   - Create Vendors in Accounts Table
   - Create Vendors in Accounts Table
   - Create Vendors of type person in Contacts Table
   - Create Vendors of type Person in Vendors Table
   - Update Vendors in Accounts Table
   - Update Vendors in Vendors Table
   - Update Vendors of type Person in Contacts Table
   - Update Vendors of type Person in Vendors Table

7. In the data factory, run the template by selecting Trigger now as shown in the following illustration. This
process might take a few hours to be completed, depending on the data volume.

**NOTE**

If you have customizations for Account, Contact, and Vendor, you must modify the template.

8. Import the new Party records into the Finance and Operations app.

   a. Download the `FONewParty.csv` file from Azure Blob storage. The path is `partybootstrapping/output/FONewParty.csv`.

   b. Convert the `FONewParty.csv` file to an Excel file, and import the Excel file into the Finance and Operations app. Alternatively, if the CSV import works for you, you can import the .csv file directly. This step might take a few hours to be completed, depending on the data volume. For more information, see Data import and export jobs overview.

9. In the data factory, run the Party postal address and Party electronic address templates, one after the other.

   - The Party postal address template upserts all postal address records in the customer engagement app, and associates them with corresponding Account, Contact, and Vendor records. It also generates three .csv files: `ImportFONewPostalAddressLocation.csv`, `ImportFONewPartyPostalAddress.csv`, and `ImportFONewPostalAddress.csv`.

   - The Party electronic address template upserts all electronic addresses in the customer engagement app, and associates them with corresponding Account, Contact, and Vendor records. It also generates one .csv file: `ImportFONewElectronicAddress.csv`. 
10. To update the Finance and Operations app with this data, you must convert the .csv files into an Excel workbook and import it into the Finance and Operations app. Alternatively, if the CSV import works for you, you can import the .csv files directly. This step might take a few hours to be completed, depending on the volume.

11. In the customer engagement app, enable the following plug-in steps:

- Account Update
  - Microsoft.Dynamics.FinanceExtended.Plugins.TriggerNotesForCustomerTypeCodes: Update of account
- Contact Update
  - Microsoft.Dynamics.GABExtended.Plugins.UpdatePartyAttributesFromContactEntity: Update of contact
  - Microsoft.Dynamics.FinanceExtended.Plugins.TriggerNotesForSellableContact: Update of contact
- msdyn_party Update
- msdyn_vendor Update
- msdyn_partypostaladdress
  - Create
Explanation of the Data Factory templates

- Microsoft.Dynamics.GABExtended.Plugins.CreateCustomerAddress: Create of msdyn_partypostaladdress
- Microsoft.Dynamics.GABExtended.Plugins.PartyPostalAddress: Create of msdyn_partypostaladdress

- Update
  - Microsoft.Dynamics.GABExtended.Plugins.CreateCustomerAddress: Update of msdyn_partypostaladdress

- msdyn_postaladdress
  - Create
    - Microsoft.Dynamics.GABExtended.Plugins.PostalAddress: Create of msdyn_postaladdress
    - Microsoft.Dynamics.GABExtended.Plugins.PostalAddressPostCreate: Create of msdyn_postaladdress
    - Microsoft.Dynamics.GABExtended.Plugins.UpdateCustomerAddress: Create of msdyn_postaladdress
  
  - Update
    - Microsoft.Dynamics.GABExtended.Plugins.PostalAddressUpdate: Update of msdyn_postaladdress
    - Microsoft.Dynamics.GABExtended.Plugins.UpdateCustomerAddress: Update of msdyn_postaladdress

- msdyn_partyelectronicaddress
  - Create
    - Microsoft.Dynamics.GABExtended.Plugins.PartyElectronicAddressSync: Create of msdyn_partyelectronicaddress
  
  - Update
  
  - Delete

12. In the customer engagement app, activate the following workflows if you previously inactivated them:

- Create Vendors in Accounts Table
- Create Vendors in Accounts Table
- Create Vendors of type person in Contacts Table
- Create Vendors of type Person in Vendors Table
- Update Vendors in Accounts Table
- Update Vendors in Vendors Table
- Update Vendors of type Person in Contacts Table
- Update Vendors of type Person in Vendors Table

13. Run the **Party** record–related maps as described in *Party and global address book.*
This section takes you through the steps in each Data Factory template.

**Steps in the Party template**

1. Steps 1 through 6 identify the companies that are enabled for dual-write and builds a filter clause for them.

2. Steps 7-1 through 7-9 retrieve data from both the Finance and Operations app and the customer engagement app, and stage that data for upgrade.

3. Steps 8 through 9 compare the party number for **Account**, **Contact**, and **Vendor** records between the Finance and Operations app and the customer engagement app. Any records that don't have a party number are skipped.

4. Step 10 generates two .csv files for the party records that must be created in the customer engagement app and the Finance and Operations app.

   - **FOCDSParty.csv** – This file contains all party records of both systems, regardless of whether the company is enabled for dual-write.
   - **FONewParty.csv** – This file contains a subset of the party records that Dataverse is aware of (for example, accounts of the **Prospect** type).

5. Step 11 creates the parties in the customer engagement app.

6. Step 12 retrieves the globally unique identifiers (GUIDs) of the parties from the customer engagement app and stages them so that they can be associated with **Account**, **Contact**, and **Vendor** records in subsequent steps.

7. Step 13 associates the **Account**, **Contact**, and **Vendor** records with party GUIDs.

8. Steps 14-1 through 14-3 update the **Account**, **Contact**, and **Vendor** records in the customer engagement app with party GUIDs.

9. Steps 15-1 through 15-3 prepare **Contact for Party** records for **Account**, **Contact**, and **Vendor** records.

10. Steps 16-1 through 16-7 retrieve reference data such as salutations and personal character types, and associate it with **Contact for Party** records.

11. Step 17 merges the **Contact for Party** records for **Account**, **Contact**, and **Vendor** records.

12. Step 18 imports the **Contact for Party** records into the customer engagement app.

**Steps in the Party postal address template**

1. Steps 1-1 through 1-10 retrieve data from both the Finance and Operations app and the customer engagement app, and stage that data for upgrade.

2. Step 2 de-normalizes the postal address data in the Finance and Operations app by joining the postal address and the party postal address.

3. Step 3 de-duplicates and merges account, contact, and vendor address data from the customer engagement app.

4. Step 4 creates .csv files for the Finance and Operations app to create new address data that is based on account, contact, and vendor addresses.

5. Step 5-1 creates .csv files for the customer engagement app to create all address data, based on both the Finance and Operations app and the customer engagement app.

   - **ImportFONewPostalAddressLocation.csv**
Steps in the Party electronic address template

1. Steps 1-1 through 1-5 retrieve data from both the Finance and Operations app and the customer engagement app, and stage that data for upgrade.

2. Step 2 consolidates electronic addresses in the customer engagement app from account, contact, and vendor entities.

3. Step 3 merges primary electronic address data from the customer engagement app and the Finance and Operations app.

4. Step 4 creates .csv files.
   - Create new electronic address data for the Finance and Operations app, based on account, contact, and vendor addresses.
   - Create new electronic address data for the customer engagement app, based on electronic address, account, contact and vendor addresses in the Finance and Operations app.

5. Step 5-1 imports electronic addresses into the customer engagement app.

6. Step 5-2 creates .csv files to update primary addresses for accounts and contacts in the customer engagement app.

7. Steps 6-1 through 6-2 import accounts and contact primary addresses into the customer engagement app.

Troubleshooting

1. If the process fails, rerun the data factory. Start from the failed activity.

2. Some files that are generated by the data factory can be used for data validation.

3. The data factory runs based on .csv files. Therefore, if a comma is included in any field value, it might interfere with the results. You must remove all commas from field values.

4. The Monitoring tab provides information about all steps and data that have been processed. Select a specific step to debug it.
Learn more about the template

For more information about the template, see Comments for Azure Data Factory template readme.
During business processes, Microsoft Dynamics 365 users often gather information about their customers. This information is recorded as activities and notes. This topic describes the integration of note data in dual-write.

Customer information can be classified in the following ways:

- **Actionable information that a Dynamics 365 user handles on behalf of a customer** – For example, Contoso (a Dynamics 365 user) is conducting a game show. One of Contoso’s customers (a customer) wants to attend the game show. The customer asks a Contoso employee to book a slot in the game show for them. The booking occurs in Contoso’s event attendee’s calendar.

- **Actionable information for a Dynamics 365 user** – For example, a customer who is purchasing a Surface unit enters special instructions that indicate that the device should be gift wrapped before delivery. These instructions are actionable information that should be handled by the Contoso employee who is responsible for packaging.

- **Non-actionable information** – For example, a customer visits the Contoso store and, during their conversation with a store associate, expresses interest in *Halo* games and gaming accessories. The store associate makes a note of this information. The product recommendations engine then uses it to make recommendations to the customer.

In general, actionable information is captured as *activities* in Finance and Operations apps and customer engagement apps. Non-actionable information is captured as *notes* in Finance and Operations apps, and as *annotations* in customer engagement apps.

**TIP**

Although notes are intended for non-actionable information, the apps won’t prevent you from using them to store and handle actionable information if you want to use them in that way.

Microsoft is currently releasing functionality for note integration. (Functionality for activity integration will be released later.) Note integration is available for customers, vendors, sales orders, and purchase orders.

**Create a note in a customer engagement app**

To create a note in a customer engagement app and then sync it to a Finance and Operations app, follow these steps.

1. In the customer engagement app, open the account record for a customer.

2. In the **Timeline** pane, select the plus sign (+), and then select **Note** to create a note.
3. Enter a title and description, and then select **Add note**.

The new note is added to the customer timeline.

4. Sign in to the Finance and Operations app, and open the same customer record. Notice that the **Attachments** button (paperclip symbol) in the upper-right corner indicates that the record has an attachment.

5. Select the **Attachments** button to open the **Attachments** page. You should find the note that you created in the customer engagement app.
Create a note in a Finance and Operations app

You can also create a note in a Finance and Operations app, and it will be synced to a customer engagement app.

To create a note in a Finance and Operations app and then sync it to a customer engagement app, follow these steps.

1. In the Finance and Operations app, on the **Attachments** page, select **New > Note**.

2. Enter a title and a brief set of instructions, and then select **Save**.

3. In the customer engagement app, update the record. You should find the new note on the timeline.
You can classify a note as either internal or external.

- In the Finance and Operations app, on the Attachments page, open the note, and then, in the Restriction field, select **Internal** or **External**.

You can also create a URL.

1. In the Finance and Operations app, on the Attachments page, select **New > URL**.
2. Enter a title and the URL.
3. In the Restriction field, select **Internal** or **External**.
4. Select **Save**.

Because customer engagement apps don't have a URL type, the URL is integrated with dual-write as a note.
NOTE

File attachments aren't supported.

Templates

Note integration includes a collection of table maps that work together during data interaction, as shown in the following table.

<table>
<thead>
<tr>
<th>FINANCE AND OPERATIONS APP</th>
<th>CUSTOMER ENGAGEMENT APP</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Customer Attachments</td>
<td>Annotations</td>
<td>Businesses that use plain text and URLs to capture customer-specific information (for both organizations and persons).</td>
</tr>
<tr>
<td>Vendor document attachments</td>
<td>Annotations</td>
<td>Businesses that use plain text and URLs to capture vendor-specific information (for both organizations and persons).</td>
</tr>
<tr>
<td>Sales order header document attachments</td>
<td>Annotations</td>
<td>Businesses that use plain text and URLs to capture sales order–specific information.</td>
</tr>
<tr>
<td>Purchase order header document attachments</td>
<td>Annotations</td>
<td>Businesses that use plain text and URLs to capture purchase order–specific information.</td>
</tr>
</tbody>
</table>

Limitations

Once you install the notes solution, you cannot uninstall it.

For more information, see Dual-write mapping reference.
Mapping tables

Mapping types
There are several different mapping types. The following table explains the symbols used in the template tables.

<table>
<thead>
<tr>
<th>SYMBOL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;</td>
<td>One-way</td>
</tr>
<tr>
<td>&gt;&gt;</td>
<td>One-way, and data is transformed in the process.</td>
</tr>
<tr>
<td>=</td>
<td>Bidirectional</td>
</tr>
<tr>
<td>&gt; &lt;</td>
<td>Bidirectional, and data is transformed in the process.</td>
</tr>
<tr>
<td>&lt; &lt;</td>
<td>One-way, and data is transformed in the process.</td>
</tr>
</tbody>
</table>

Filters
The source filter and reverse source filter determine which rows are synchronized.

Default values
If a synchronized field does not exist in either the finance and operations table or the customer engagement table, then a default value is assigned in the synchronized table. In some cases, the default value is an integer that is a lookup to an attribute value in Dataverse. For example, in the Contact table, the default value for address1AddressTypeCode is 3 (Primary address).

Support for Field Service solutions

Microsoft supports dual-write on top of existing Dataverse environments that are based on Field Service solutions.

For more information, see Integrate Dynamics 365 Field Service and Supply Chain Management.

Support for Project Service Automation solutions

Microsoft supports dual-write on top of existing Dataverse environments that are based on Project Service Automation solutions.
To migrate your Prospect to cash data from Data Integrator to dual-write, follow these steps.

1. Run the Prospect to cash Data Integrator jobs to do one final full synchronization. In this way, you ensure that both systems (Finance and Operations apps and customer engagement apps) have all the data.

2. To help prevent potential data loss, export the Prospect to cash data from Microsoft Dynamics 365 Sales to an Excel file or a comma-separated values (CSV) file. Export data from the following entities:
   - Account
   - Contact
   - Invoice
   - Invoice products
   - Order
   - Order products
   - Products
   - Quote
   - Quote products

3. Uninstall the Prospect to cash solution from the Sales environment. This step removes the columns and corresponding data that the Prospect to cash solution introduced.

4. Install the dual-write solution.

5. Create a dual-write connection between the Finance and Operations app and the customer engagement app for one or more legal entities.

6. Enable dual-write table maps, and run the initial synchronization for the required reference data. (For more information, see Considerations for initial synchronization.) Examples of required data include customer groups, payment terms, and payment schedules. Don't enable the dual-write maps for tables that require initialization, such as the account, quote, quote line, order, and order line tables.

7. In the customer engagement app, go to Advanced Settings > System Settings > Data Management > Duplicate detection rules, and disable all the rules.

8. Initialize the tables that are listed in step 2. For instructions, see the remaining sections of this topic.

9. Open the Finance and Operations app, and enable the table maps, such as the account, quote, quote line, order, and order line table maps. Then run the initial synchronization. (For more information, see Considerations for initial synchronization.) This process will sync additional information from the Finance and Operations app, such as processing status, shipping and billing addresses, sites, and warehouses.

**Account table**

1. In the **Company** column, enter the company name, such as **USMF**.

2. In the **Relationship Type** column, enter **Customer** as a static value. You might not want to classify every account record as a customer in your business logic.

3. In the **Customer Group ID** column, enter the customer group number from the Finance and Operations
app. The default value from the Prospect to cash solution is 10.

4. If you're using the Prospect to cash solution without any customization of Account Number, enter an Account Number value in the Party Number column. If there are customizations, and you don't know the party number, pull this information from the Finance and Operations app.

Contact table

1. In the Company column, enter the company name, such as USMF.

2. Set the following columns, based on the IsActiveCustomer value in the CSV file:
   - If IsActiveCustomer is set to Yes in the CSV file, set the Sellable column to Yes. In the Customer Group ID column, enter the customer group number from the Finance and Operations app. The default value from the Prospect to cash solution is 10.
   - If IsActiveCustomer is set to No in the CSV file, set the Sellable column to No, and set the Contact For column to Customer.

3. If you're using the Prospect to cash solution without any customization of Contact Number, set the following columns:
   - Migrate the contact number from the CSV file (msdynce_contactnumber) to the contact number in the Contact table (msdyn_contactnumber).
   - Use values from the Contact Number table in the Party Number column.
   - Use values from the Contact Number table in the Account Number/Contact Person ID column.

Invoice table

Because data from the Invoice table is designed to flow one way, from the Finance and Operations app to the customer engagement app, initialization isn't required. Run the initial synchronization to migrate all the required data from the Finance and Operations app to the customer engagement app. For more information, see Considerations for initial synchronization.

Order table

1. In the Company column, enter the company name, such as USMF.

2. Copy the value of the Order ID column in the CSV file to the Sales Order Number column.

3. Copy the value of the Customer column in the CSV file to the Invoice customer number column.

4. Copy the value of the Ship To Country/Region column in the CSV file to the Ship To Country/Region column. Examples of this value include US and United States.

5. Set the Requested Receipt Date column. If you aren't using a receipt date, use the Requested Delivery Date, Date Fulfilled, and Date Submitted columns in the CSV file. An example of this value is 2020-03-27T00:00:00Z.

6. Set the Language column. An example of this value is en-us.

7. Set the Order Type column by using the Item-based column.

Order products table

- In the Company column, enter the company name, such as USMF.

Products table

Because data from the Products table is designed to flow one way, from the Finance and Operations app to the customer engagement app, initialization isn't required. Run the initial synchronization to migrate all the required data from the Finance and Operations app to the customer engagement app. For more information, see
Considerations for initial synchronization.

Quote and Quote product tables

For the Quote table, follow the instructions in the Order table section earlier in this topic. For the Quote product table, follow the instructions in the Order products table section.
This topic provides general troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse.

**IMPORTANT**
Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

---

Enable and view the plug-in trace log in Dataverse to view error details

**Required role to turn on the trace log and view errors:** System admin

To turn on the trace log, follow these steps.

1. Sign in to the customer engagement app, open the **Settings** page, and then, under **System**, select **Administration**.
2. On the **Administration** page, select **System Settings**.
3. On the **Customization** tab, in the **Plug-in and custom workflow activity tracing** column, select **All** to enable the plug-in trace log. If you want to log trace logs only when exceptions occur, you can select **Exception** instead.

To view the trace log, follow these steps.

1. Sign in to the customer engagement app, open the **Settings** page, and then, under **Customization**, select **Plug-in Trace Log**.
2. Find the trace logs where the **Type Name** column is set to **Microsoft.Dynamics.Integrator.DualWriteRuntime.Plugins.PreCommmitPlugin**.
3. Double-click an item to view the full log, and then, on the **Execution** FastTab, review the **Message Block** text.

---

Enable debug mode to troubleshoot live synchronization issues in Finance and Operations apps

**Required role to view the errors:** System admin

Dual-write errors that originate in Dataverse can appear in the Finance and Operations app. To enable verbose logging for the errors, following these steps:

1. For all project configurations in Finance and Operations app there is a flag **IsDebugMode** on the **DualWriteProjectConfiguration** table.
2. Open the **DualWriteProjectConfiguration** using the Excel addin. To use the addin, enable design mode in the Finance and Operations Excel addin and add the **DualWriteProjectConfiguration** to the sheet. For more information, see View and update entity data with Excel.
3. Set **IsDebugMode** to Yes on the project.
4. Run the scenario that is generating errors.
5. The verbose logs are stored in the **DualWriteErrorLog** table.

6. To lookup data on table browser use the following link:
   
   https://999aos.cloudax.dynamics.com/?mi=SysTableBrowser&tableName=DualWriteErrorLog, replacing **999** as needed.

7. Update again after **KB 4595434**, which is available for platform updates 37 and later. If you have this fix installed then the debug mode will capture more logs.

**Check synchronization errors on the virtual machine for the Finance and Operations app**

**Required role to view the errors:** System administrator

1. Sign in to Microsoft Dynamics Lifecycle Services (LCS).
2. Open the LCS project that you chose to do the dual-write testing for.
3. Select the **Cloud-hosted environments** tile.
4. Use Remote Desktop to sign in to the virtual machine (VM) for the Finance and Operations app. Use the local account that is shown in LCS.
5. Open Event viewer.
6. Select **Applications and Services Logs > Microsoft > Dynamics > AX-DualWriteSync > Operational**.
7. Review the list of recent errors.

**Unlink and link another Dataverse environment from a Finance and Operations app**

**Required role to unlink the environment:** System administrator for either Finance and Operations app or Dataverse.

1. Sign in to the Finance and Operations app.
2. Go to **Workspaces > Data management**, and select the **Dual Write** tile.
3. Select all running mappings, and then select **Stop**.
4. Select **Unlink environment**.
5. Select **Yes** to confirm the operation.

You can now link a new environment.

**Unable to view the sales order line Information form**

When you create a sales order in Dynamics 365 Sales, clicking on **+ Add products** might redirect you to the Dynamics 365 Project Operations order line form. There is no way from that form to view the sales order line **Information** form. The option for **Information** does not appear in the dropdown below **New Order Line**. This happens because Project Operations has been installed in your environment.

To re-enable the **Information** form option, follow these steps:

1. Navigate to the **Order Line** table.
2. Find the **Information** form under the forms node.
3. Select the **Information** form and click **Enable security roles**.
4. Change the security setting to **Display to everyone**.

**How to enable and save network trace so that traces can be attached**
to support tickets

The support team might need to review network traces to troubleshoot some issues. To create a network track, follow these steps:

**Chrome**

1. In the opened tab, press F12 or choose Developer tools to open the developer tools.
2. Open the Network tab and type integ in the filter text box.
3. Run your scenario and observe the requests being logged.
4. Right-click on the entries and select Save all as a HAR with content.

**Microsoft Edge**

1. In the opened tab, press F12 or choose Developer tools to open the developer tools.
2. Open the Network tab.
3. Run your scenario.
4. Select save to export the results as HAR.
This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues that might occur during the initial setup of dual-write integration.

**IMPORTANT**

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

---

**You can't link a Finance and Operations app to Dataverse**

**Required role to set up dual-write:** System administrator in Finance and Operations apps and Dataverse.

Errors on the Setup link to Dataverse page are usually caused by incomplete setup or permissions issues. Make sure that the whole health check passes on the Setup link to Dataverse page, as shown in the following illustration. You can't link dual-write unless the whole health check passes.

---

You must have Azure AD tenant admin credentials to link the Finance and Operations and Dataverse environments. After you link the environments, users can sign in by using their account credentials and update an existing table map.
Find the limit on the number of legal tables or companies that can be linked for dual-write

You might receive the following error message when you try to enable maps:

_Dual write failure - Plugin registration failed: [Unable to get partition map for project DWM-1ae35e60-4bc2-4905-88ea-69efd3b29260-7f12cb89-1550-42e2-858e-4761fc1443ea. Error Exceeds the maximum partitions allowed for mapping DWM-1ae35e60-4bc2-4905-88ea-69efd3b29260-7f12cb89-1550-42e2-858e-4761fc1443ea]_. One or more errors occurred.

The current limit when you link the environments is approximately 40 legal tables. This error occurs if you try to enable maps, and more than 40 legal tables are linked between the environments.

**Connection set failed while linking environment**

While linking the dual-write environment, the action fails with an error message:

_Saving connection set failed! An item with the same key has already been added._

_Dual-write does not support multiple legal entities/companies with the same name. For example, If you have two companies with "DAT" name in the Dataverse then it will get this error message._

To unblock the customer, remove duplicate records from _cdm_company_ table in Dataverse. Also, if the _cdm_company_ table has records with blank name, remove or correct those records.

**Error when opening the Dual-write page in Finance and Operations apps**

You might receive the following error message when you try to link a Dataverse environment for dual-write:

_Response status code does not indicate success: 404 (Not Found)._

This error occurs when the app consent step is not complete. You can validate if consent has been provided by logging on to _portal.azure.com_ using the tenant admin account, and check if the 3rd party app with ID _33976c19-1db5-4c02-810e-c243db79efde_ shows up in AAD’s Enterprise applications list. If not, then rerun the consent step as described in the next section.

**Providing App consent**

- Launch the following URL with your admin credentials.

  https://login.microsoftonline.com/common/oauth2/authorize?client_id=33976c19-1db5-4c02-810e-c243db79efde&response_type=code&prompt=admin_consent

- Select _Accept_ to consent. You are providing the consent to install the app (with _id=33976c19-1db5-4c02-810e-c243db79efde_) in your tenant.

- This app is required for Dataverse to communicate to Finance and Operations apps.
Finance and Operations environment is not discoverable

You might receive the following error message:

*Finance and Operations apps environment ***.cloudax.dynamics.com is not discoverable.*

There are two things that can cause an issue with environment not being discoverable:

- The user used for login is not in the same tenant as the Finance and Operations instance.
- There are some legacy Finance and Operations instances that were Microsoft-hosted that had an issue with discovery. To fix this, update the Finance and Operations instance. The environment becomes discoverable with any update.
This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues that might occur during initial synchronization.

**IMPORTANT**

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

Check for initial synchronization errors in a Finance and Operations app

After you enable the mapping templates, the status of the maps should be Running. If the status is Not running, errors occurred during initial synchronization. To view the errors, select the Initial sync details tab on the Dual-write page.

You can't complete initial synchronization: 400 Bad Request

**Required role to fix the issue:** System admin

You might receive the following error message when you try to run the mapping and initial synchronization:

```
[(Bad Request), The remote server returned an error: (400) Bad Request), AX export encountered an error.
```

Here is an example of the full error message.
Dual write Initial Sync completed with status: Error. Following are the details:

Executed leg: From AX Financial dimensions to CRM msdyn_dimensionattributes
with exported records count: 0, ImportRecordsErrorCount: 0, ImportRecordsInsertedCount: 0 and ImportRecordsUpdatedCount: 0

ErrorsDetails:
Dual write Initial sync failed
Message: ([Bad Request], The remote server returned an error: (400) Bad Request.), AX export encountered an error

Stacktrace: at
in X:\bt\1024532\repo\src\Core\QueryGenerator\AxClient.cs:line 265
--- End of stack trace from previous location where exception was thrown ---
at System.Runtime.ExceptionServices.ExceptionDispatchInfo.Throw()
at System.Runtime.CompilerServices.TaskAwaiter.HandleNonSuccessAndDebuggerNotification(Task task)
The error messages that you receive will have the following form.

*Couldn't resolve the guid for the field: <field>. The lookup was not found: <value>.* Try this URL(s) to check if the reference data exists:

```
https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/entity?$select=<field>&$filter=<field> eq <value>
```

Here are some examples:

- *Couldn't resolve the guid for the field: msdyn_vendorprimarycontactperson.msdyn_contactpersonid. The lookup was not found: 000056.* Try this URL(s) to check if the reference data exists:
  
  ```
  https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/contacts?
  $select=msdyn_contactpersonid/contactid&$filter=msdyn_contactpersonid eq '000056'
  ```

- *Couldn't resolve the guid for the field: msdyn_invoicevendoraccountnumber.msdyn_vendoraccountnumber. The lookup was not found: V24-1.* Try this URL(s) to check if the reference data exists:
  
  ```
  https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/msdn_vendors?
  $select=msdyn_vendoraccountnumber,msdyn_vendorid&$filter=msdyn_vendoraccountnumber eq 'V24-1'
  ```

If any rows in the vendor table have values in the `PrimaryContactPersonId` and `InvoiceVendorAccountNumber` columns, follow these steps to complete the initial synchronization.

1. In the Finance and Operations app, delete the `PrimaryContactPersonId` and `InvoiceVendorAccountNumber` columns from the mapping, and then save the mapping.

   a. On the dual-write mapping page for **Vendors V2 (msdyn_vendors)**, on the **Table mappings** tab, in the left filter, select **Finance and Operations apps.Vendors V2**. In the right filter, select **Sales.Vendor**.

   b. Search for `primarycontactperson` to find the `PrimaryContactPersonId` source column.

   c. Select **Actions**, and then select **Delete**.

   d. Repeat these steps to delete the `InvoiceVendorAccountNumber` column.

   e. Save your changes to the mapping.

2. Turn off change tracking for the **Vendors V2** table.

   a. In the **Data management** workspace, select the **Data tables** tile.

   b. Select the **Vendors V2** table.

   c. On the Action Pane, select **Options**, and then select **Change tracking**.
d. Select **Disable Change Tracking**.

3. Run initial synchronization for the **Vendors V2 (msdyn_vendors)** mapping. The initial synchronization should run successfully, without any errors.

4. Run initial synchronization for the **CDS Contacts V2 (contacts)** mapping. You must sync this mapping if you want to sync the primary contact column on the vendors table, because initial synchronization must also be done for the contact rows.

5. Add the **PrimaryContactPersonId** and **InvoiceVendorAccountNumber** columns back to the **Vendors V2 (msdyn_vendors)** mapping, and then save the mapping.

6. Run initial synchronization again for the **Vendors V2 (msdyn_vendors)** mapping. Because change tracking is turned off, all the rows will be synced.

7. Turn change tracking back on for the **Vendors V2** table.

**Resolve errors in the Customers V3–to–Accounts table mapping**

You might encounter initial synchronization errors for the mapping of **Customers V3** to **Accounts** if the tables have existing rows where there are values in the **ContactPersonID** and **InvoiceAccount** columns. These errors occur because **InvoiceAccount** is a self-referencing column, and **ContactPersonID** is a circular reference in the vendor mapping.

The error messages that you receive will have the following form.

*Couldn't resolve the guid for the field: <field>. The lookup was not found: <value>. Try this URL(s) to check if the reference data exists:*

```
https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/<entity>?$select=<field>&$filter=<field> eq <value>
```

Here are some examples:

- *Couldn’t resolve the guid for the field: primarycontactid.msdyn_contactpersonid. The lookup was not found: 000056. Try this URL(s) to check if the reference data exists:*

  ```
  https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/contacts?$select=msdyn_contactpersonid.contactid&$filter=msdyn_contactpersonid eq '000056'
  ```

- *Couldn’t resolve the guid for the field: msdyn_billingaccount.accountnumber. The lookup was not found: 1206-1. Try this URL(s) to check if the reference data exists:*

  ```
  https://focdsdevtest2.crm.dynamics.com/api/data/v9.0/accounts?$select=accountnumber.account&$filter=accountnumber eq '1206-1'
  ```
If any rows in the customer table have values in the ContactPersonID and InvoiceAccount columns, follow these steps to complete the initial synchronization. You can use this approach for any out-of-box tables, such as Accounts and Contacts.

1. In the Finance and Operations app, delete the ContactPersonID and InvoiceAccount columns from the Customers V3 (accounts) mapping, and then save the mapping.
   b. Search for contactperson to find the ContactPersonID source column.
   c. Select Actions, and then select Delete.
   d. Repeat these steps to delete the InvoiceAccount column.
   e. Save your changes to the mapping.

2. Turn off change tracking for the Customers V3 table.
   a. In the Data management workspace, select the Data tables tile.
   b. Select the Customers V3 table.
   c. On the Action Pane, select Options, and then select Change tracking.
   d. Select Disable Change Tracking.
3. Run initial synchronization for the Customers V3 (Accounts) mapping. The initial synchronization should run successfully, without any errors.

4. Run initial synchronization for the CDS Contacts V2 (contacts) mapping.

   **NOTE**
   There are two maps that have the same name. Be sure to select the map that has the following description on the Details tab: Dual-write template for sync between FO.CDS Vendor Contacts V2 to CDS.Contacts. Requires new package [Dynamics365SupplyChainExtended].

5. Add the InvoiceAccount and ContactPersonId columns back to the Customers V3 (Accounts) mapping, and then save the mapping. Both the InvoiceAccount column and the ContactPersonId column are now part of live synchronization mode again. In the next step, you will do the initial synchronization for these columns.

6. Run initial synchronization again for the Customers V3 (Accounts) mapping. Because change tracking is turned off, the data for InvoiceAccount and ContactPersonId will be synced from the Finance and Operations app to Dataverse.

7. To sync the data for InvoiceAccount and ContactPersonId from Dataverse to the Finance and Operations app, you must use a data integration project.

   a. In Power Apps, create a data integration project between the Sales.Account and Finance and Operations apps.Customers V3 tables. The data direction must be from Dataverse to the Finance and Operations app. Because InvoiceAccount is a new attribute in dual-write, you might want to skip initial synchronization for it. For more information, see Integrate data into Dataverse.

   The following illustration shows a project that updates CustomerAccount and ContactPersonId.

   ![Project Illustration]

   b. Add the company criteria in the filter on the Dataverse side, so that only rows that match the filter criteria will be updated in the Finance and Operations app. To add a filter, select the filter button. Then, in the Edit query dialog box, you can add a filter query such as _msdyn_company_value eq '<guid>'.
If you don't enter a filter query for `_msdyn_company_value`, all the rows will be synced.

The initial synchronization of the rows is now completed.

8. In the Finance and Operations app, turn change tracking back on for the Customers V3 table.

**Initial sync failures on maps with more than 10 lookup fields**

You might receive the following error message when you try run an initial sync failures on Customers V3 - Accounts, Sales orders mappings, or any map with more than 10 lookup fields:

`CRMExport: Package execution complete. Error Description 5 Attempts to get data from https://xxxxx//datasets/yyyyy/tables/accounts/items?$select=accountnumber, address2_city, address2_country,... (msdyn_company/cdm_companyid eq 'id')&$orderby=accountnumber asc failed.`

Because of the lookup limitation on the query, the initial sync fails when the entity mapping contains more than 10 lookups. For more information, see [Retrieve related table records with a query](#).

To fix this issue, follow these steps:

1. Remove optional lookup fields from the dual-write entity map so that the number of lookups is 10 or fewer.
2. Save the map and do the initial sync.
3. When the initial sync for the first step is successful, add the remaining lookup fields and remove the lookup fields that you synced in first step. Make sure that the number of lookup fields is 10 or fewer. Save the map and run the initial sync.
4. Repeat these steps until all the lookup fields are synced.
5. Add all the lookup fields back to the map, save the map, and run the map with Skip initial sync.

This process enables the map for live sync mode.

**Known issue during initial sync of Party postal addresses and party electronic addresses**

You might receive the following error message when you try to run the initial syn of Party postal addresses and party electronic addresses:

`Party number could not found in Dataverse.`
There is a range set on `DirPartyCDSEntity` in Finance and Operations apps that filters parties of type `Person` and `Organization`. As a result, an initial sync of the `CDS Parties – msdyn_parties` mapping will not sync parties of other types, including `Legal Entity` and `Operating Unit`. When the initial sync runs for `CDS Party postal addresses (msdyn_partypostaladdresses)` or `Party Contacts V3 (msdyn_partyelectronicaddresses)` you might receive the error.

We are working on a fix to remove the party type range on the Finance and Operations entity so that parties of all types can synchronize to Dataverse successfully.

**Are there any performance issues while running initial sync for Customers or Contacts data?**

If you have run the initial sync for `Customer` data and have the `Customer` maps running and then you are run the initial sync for `Contacts` data, there might be performance issues during inserts and updates to the `LogisticsPostalAddress` and `LogisticsElectronicAddress` tables for `Contact` addresses. The same global postal address and electronic address tables are tracked for `CustCustomerV3Entity` and `VendVendorV2Entity` and dual-write tries to build more queries to write data to other side. If you have already run the initial sync for `Customer`, then stop the corresponding map while running initial sync for `Contacts` data. Do the same thing for the `Vendor` data. When the initial sync is finished, you can run all the maps by skipping the initial sync.
This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Microsoft Dataverse. Specifically, it provides information that can help you fix issues with live synchronization.

**IMPORTANT**

Some of the issues that this topic addresses might require either the system admin role or Azure Active Directory (Azure AD) tenant admin credentials. Each section explains whether a specific role or specific credentials are required.

---

**Live synchronization shows an error when you create a row**

You might receive the following error message when you create a row in a Finance and Operations app:

```javascript

{"error":{"code":"0x80072560","message":"The user is not a member of the organization."}, The remote server returned an error: (403) Forbidden.

```

To fix the issue, follow the steps in System requirements and prerequisites. To complete those steps, dual-write application users who were created in Dataverse must have the system admin role. The default owning team must also have the system admin role.

**Required role to fix the issue:** System admin

---

**Live synchronization shows an error when you try to save table data**

You might receive the following error message when you try to save table data in a Finance and Operations app:

```

Cannot save the changes to the database. Unit of Work can not commit transaction. Unable to write data to entity uoms. Writes to UnitOfMeasureEntity failed with error message Unable to sync with entity uoms.

```

To fix the issue, make sure that prerequisite reference data exists in both the Finance and Operations app and Dataverse. For example, if a customer record belongs to a specific customer group, make sure that the customer group record exists in Dataverse.

If data exists in both places, and you’ve confirmed that the issue isn’t data related, follow these steps.

1. Open the DualWriteProjectConfigurationEntity entity by using the Excel add-in. To use the add-in, enable design mode in the Finance and Operations Excel add-in, and add DualWriteProjectConfigurationEntity to a worksheet. For more information, see View and update entity data with Excel.

2. Select and delete the records that have issues in the dual-write map and project. There will be two records for every dual-write mapping.

3. Publish the changes by using the Excel add-in. This step is important because it deletes the records from the entity and underlying tables.

---

**Handle read or write privilege errors when you create data in a Finance and Operations app**

You might receive a “Bad Request” error message when you create data in a Finance and Operations app.
To fix the issue, you must enable the missing privilege by assigning the correct security role to the team of mapped Dynamics 365 Sales or Dynamics 365 Customer Service business units.

1. In the Finance and Operations app, find the business unit that is mapped in the Data Integration connection set.

2. In the customer engagement app, sign in to the environment, go to Setting > Security, and find the team of the mapped business unit.

3. Open the page for the team for editing, and then select Manage roles.

4. In the Manage Team Roles dialog box, assign the role that has the read/write privilege for the relevant
Fix synchronization issues in an environment that has a recently changed Dataverse environment

**Required role to fix the issue:** System admin

You might receive the following error message when you create data in a Finance and Operations app:

```json
{ "entityName": "CustCustomerV3Entity", "executionStatus": 2, "fieldResponses": [], "recordResponses": [{ "errorMessage": "Unable to generate payload for entity CustCustomerV3Entity", "logDateTime": "2019-08-27T18:51:52.5843124Z", "verboseError": "Payload creation failed with error Invalid URI: The URI is empty."
}, { "isErrorCountUpdated": true }]}
```

Here is the error message in the customer engagement app:

```
An unexpected error occurred from ISV code. (ErrorType = ClientError) Unexpected exception from plug-in (Execute): Microsoft.Dynamics.Integrator.DualWriteRuntime.Plugins.PostCommitPlugin: System.Exception: failed to process entity account - (A connection attempt failed because the connected party did not properly respond after a period of time, or established connection failed because connected host has failed to respond.
```

This error occurs if the Dataverse environment is incorrectly reset when you try to create data in the Finance and Operations app.

**IMPORTANT**

If you’ve relinked the environments, you must stop all the entity maps before you continue with the mitigation steps.

To fix the issue, you must complete steps in both Dataverse and the Finance and Operations app.

1. In the Finance and Operations app, follow these steps:
   a. Open the DualWriteProjectConfigurationEntity entity by using the Excel add-in. To use the add-in, enable design mode in the Finance and Operations Excel add-in, and add DualWriteProjectConfigurationEntity to a worksheet. For more information, see View and update entity data with Excel.
   b. Select and delete the records that have issues in the dual-write map and project. There will be two records for every dual-write mapping.
   c. Publish the changes by using the Excel add-in. This step is important because it deletes the records from the entity and underlying tables.
   d. To help prevent errors when you relink the Finance and Operations or Dataverse environments, make sure that no dual-write configurations remain.

2. In Dataverse, follow these steps:
   a. Sign in to your Dataverse environment (for example, [https://****.crm.dynamics.com/](https://****.crm.dynamics.com/) ).
   b. Go to Advanced Settings > Advanced Find.
   c. Select DualWrite Runtime Configuration.
   d. Select the column to view.
   e. Select Results to view the configurations.
   f. Delete all the instances.

3. In the Finance and Operations app, follow these steps:
Live synchronization error after you do a full database copy

You might receive the following error message after you run a full database copy from one system to another and then try to run a database operation:

SecureConfig Organization (???) does not match actual CRM Organization (???).

The error message is shown from the dual-write runtime plug-in to ensure that the dual-write configuration that is set up in one system can't be used in another system.

To fix the issue, delete all the records in the msdyn_dualwriteruntimeconfig table after you restore the database. For more information, see Unlink and relink dual-write environments.

Live synchronization issues that are caused by incorrect query filter syntax on the dual-write maps

Even though the query expression for a dual-write map filter is syntactically correct, it might not work as expected. The filter expression is on an entity, not on an individual data source of a query object. Therefore, the SQL query that is generated doesn't return the expected results.

Here is an example.

You might expect projects that have no parent to be filtered out. However, the filter doesn't work because it's translated to a query that resembles the following example.

```
SELECT T1.RECID,T1.MODIFIEDDATETIME,T1.RECVERSION,T1.RECID,T1.DIMENSION,
   T1.LOCATION,T1.PROJECTCONTROLLER,T1.PROJECTID,T1.PROJECTMANAGER,T1.REFERENCE,
   T1.SALESMANAGER,T1.SCHEDULED,T1.RECVERSION#8,T1.RECVERSION#7,
   T1.RECVERSION#6,T1.RECVERSION#5,T1.RECVERSION#4,T1.RECVERSION#3,
   T1.RECVERSION#2,T1.RECID#8,T1.RECID#7,T1.RECID#6,T1.RECID#5,
   T1.RECID#4,T1.RECID#3,T1.RECID#2,T1.PARTITION FROM PROJECTENTITY T1
WHERE((((((((((((PARTITION=5637144576) AND (DATAAREAID=N'usmf')) AND
   (PARTITION#2=5637144576) OR (PARTITION#2 IS NULL)) AND
   (PARTITION#3=5637144576) OR (PARTITION#3 IS NULL)) AND
   (PARTITION#4=5637144576) OR (PARTITION#4 IS NULL)) AND
   (PARTITION#5=5637144576) OR (PARTITION#5 IS NULL)) AND
   (PARTITION#6=5637144576) OR (PARTITION#6 IS NULL)) AND
   (PARTITION#7=5637144576) OR (PARTITION#7 IS NULL)) AND
   (PARTITION#8=5637144576) OR (PARTITION#8 IS NULL)) AND
   (PARENTPROJECT=''))
ORDER BY T1.PROJECTID
```
The actual result is that the `ParentProject` field is evaluated to `null`. However, `null` isn't the same as the empty string. Because of this mismatch, the query filter doesn't return valid results.

To fix the issue, follow these steps.

1. Add a computed column that can be added in an extension model, and that is backed by logic that converts `null` to the empty string.

   ```x++
   SysComputedColumn::if(SysComputedColumn::isNullExpression(ParentProject),
   SysComputedColumn::returnLiteral(""), fieldName);
   ```

2. Use the filter on the new computed column instead of the default column.

To evaluate the filter in a development environment, you can use following X++ code to validate the results. Run this code as a standalone program. You can use it to evaluate different kinds of filters that are applicable for an entity before you use those filters on dual-write maps. The query can be run against the database to evaluate discrepancies.

```x++
var entityName = "PROJECTENTITY";
var filterExpression = '(ParentProject == ")
Query query = new Query();
query.literals(NoYes::Yes);
QueryBuildDataSource qbd = query.addDataSource tablename2Id(entityName));
qbd.addRange(fieldname2id(qbd.table(), identifierStr(RecVersion))).value(filterExpression);
qbd.addSelectionField(fieldname2id(qbd.table(), identifierStr(RecId)));
QueryRun qRun = new QueryRun(query);
// This provides the actual sql statement to execute
var actualSqlStatement = query.getSQLStatement();
while(qRun.next())
{
    var rec = qRun.get(tableName2Id(entityName));
}
```

Data from Finance and Operations apps isn't synced to Dataverse

During live synchronization, you might encounter an issue where only part of the data is synced from Finance and Operations apps to Dataverse, or data isn't synced at all.

**NOTE**
You must fix this issue during development.

Before you start to fix the issue, review the following prerequisites:

- Make sure that your custom changes are written in a single transaction scope.
- Business events and the dual-write framework don't handle `doinsert()`, `doUpdate()`, and `recordset()` operations, or records where `skipBusinessEvents(true)` is marked. If your code is inside these functions, dual-write won't be triggered.
- Business events must be registered for the data source that is mapped. Some data sources might use an outer join and might be marked as read only in Finance and Operations apps. These data sources aren't tracked.
- Changes will be triggered only if the modifications are on the mapped fields. Unmapped field modifications won't trigger dual-write.
- Make sure that filter evaluations provide a valid result.

**Troubleshooting steps**
1. Review field mappings on the dual-write admin page. If a field isn't mapped from Finance and Operations apps to Dataverse, it won't be tracked. For example, in the following illustration, the **Description** field is tracked from Dataverse, but not from Finance and Operations apps. No changes to that field inside Finance and Operations apps will be tracked.

![Image of field mappings](image1.png)

2. Determine whether the data source is tracked in the business events definition. For example, in the following illustration, no field from the **DefaultDimensionDAVs** table and underlying tables will be tracked for changes. Data sources that use an outer join and that are marked as read only aren't tracked.

![Image of business events definition](image2.png)

3. Determine whether the mapped table fields appear in the **BUSINESSEVENTSDEFINITION** table, as shown in the following illustration. If you don't find the field that you're looking for in the query result, it won't be triggered by dual-write.

![Image of query result](image3.png)
Sample scenario

In Finance and Operations apps, there is an update to the address for a contact record, but the address change isn’t synced to Dataverse. This scenario occurs because no record in the BusinessEventsDefinition table has the combination of the affected table and the entity. Specifically, the LogisticsPostalAddress table isn’t the direct data source for the smmContactpersonCDSV2Entity entity. The smmContactpersonCDSV2Entity entity has smmContactPersonV2Entity as the data source, and smmContactPersonV2Entity, in turn, has LogisticsPostalAddressBaseEntity as the data source. The LogisticsPostalAddress table is the data source for LogisticsPostalAddressBaseEntity.

A similar situation can occur in some non-standard patterns, such as cases where the table that is being modified in Finance and Operations apps isn’t obviously linked to the entity that contains it. For example, the primary address data is computed on the smmContactPersonCDSV2Entity entity. The dual-write framework tries to determine how a change to an underlying table is mapped back to entities. Usually, this approach is sufficient. However, in some cases, the link is so complex that you must be specific. You must make sure that the RecId of the related table is directly available on the entity. Then add a static method to monitor the table for changes.

For an example, review the smmContactPersonCDSV2Entity::getEntityDataSourceToFieldMapping() method. CustCustomerV3entity and VendVendorV2Entity have been modified to handle this situation.

To fix the issue, follow these steps.

1. Add a PrimaryPostalAddressRecId field to the smmContactPersonV2Entity entity. Make it internal.

2. Add the same field to the smmContactPersonCDSV2Entity entity.
Error when you create a record where multiple records are sent from a Finance and Operations app to Dataverse in the same batch

For any transaction, a Finance and Operations app creates data in a batch and sends it as a batch to Dataverse. If two records are created as part of the same transaction, and they reference each other, you might receive an error message that resembles the following example in the Finance and Operations app:

Unable to write data to entity aaa_fundingsources. Un... Unable to lookup ebecsf_s_contracts with values {PC00...}. Unable to lookup aaa_fundingsources with values {PC00...}. Writes to aaa_fundingsources failed with error message: The remote server returned an error: (400) Bad Request.

To fix the issue, create entity relationships in the Finance and Operations app to indicate that the two entities are related to each other, and that the related records are handled in the same transaction.

Enable verbose logging of error messages

In a Finance and Operations app, you might encounter errors that are related to the Dataverse environment. The error message might not contain the full text of the message or other relevant data. To get more information, you can enable verbose logging by setting the IsDebugMode flag that is present on the DualWriteProjectConfigurationEntity entity in all project configurations in Finance and Operations apps.

1. Open the DualWriteProjectConfigurationEntity entity by using the Excel add-in. To use the add-in, enable design mode in the Finance and Operations Excel add-in, and add DualWriteProjectConfigurationEntity to a worksheet. For more information, see View and update entity data with Excel.
2. Set the IsDebugMode flag to Yes on the project.
3. Run the scenario.
4. The verbose logs are available in the DualWriteErrorLog table. To look up data by using the table browser, use the following URL: https://XXXaos.cloudax.dynamics.com/?mi=SysTableBrowser&tableName=DualWriteErrorLog
5. To capture more logs in debug mode, install the update in KB 4595434 (Fix for blank values being propagated in Dual write live sync).

Error when you add an address for a customer or contact

You might receive the following error message when you try to add an address for a customer or contact in Finance and Operations apps or Dataverse:

*Unable to write data to entity msdyn_partypostaladdresses.Writes to DirPartyPostalAddressLocationCDSEntity failed with error message Request failed with status code BadRequest and CDS error code : 0x80040265 response message: An error occurred in plugin. A record that has the attribute values Location ID already exists. The entity key Location ID Key requires that this set of attributes contains unique values. Select unique values and try again.*

To fix the issue, install the dual-write orchestration package version (2.2.2.60), so that the keys on the Address table are defined as shown in the following table.

<table>
<thead>
<tr>
<th>PROPERTY</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display Name</td>
<td>Location Key</td>
</tr>
<tr>
<td>Name</td>
<td>msdyn_locationkey</td>
</tr>
<tr>
<td>Fields</td>
<td>msdyn_locationid, parentid</td>
</tr>
<tr>
<td>Status</td>
<td>Active</td>
</tr>
<tr>
<td>System job</td>
<td>Blank</td>
</tr>
</tbody>
</table>

Error when you add a customer in Dataverse

You might receive the following error message when you try to add a customer in Dataverse:

"RecordError0":"Write failed for entity Customers V3 with unknown exception - Party record not found for party type 'Organization')."

When a customer is created in Dataverse, a new party number is generated. The error message is shown when the customer record, together with the party, is synced to Finance and Operations apps, but there is already a customer record that has a different party number.

To fix the issue, find the customer through party lookup. If the customer doesn’t exist, create a new customer record. If the customer does exist, use the existing party to create the new customer record.

Error when you create a new customer, vendor, or contact in Dataverse

You might receive the following error message when you try to create a new customer, vendor, or contact in Dataverse:

*Cannot update a party’s type from 'DirOrganization' to 'DirPerson', a delete of the existing party followed by an insert with the new type should be performed instead.*

In Dataverse, there is a number sequence on the msdyn_party table. When an account is created in Dataverse, a new party is created (for example Party-001 of the Organization type). This data is sent to the Finance and
Operations app. If the Dataverse environment is reset, or the Finance and Operations environment is linked to a different Dataverse environment, and then a new contact record is created in Dataverse, a new party value that starts with Party-001 is created. This time, the party record that is created will be Party-001 of the Person type. When this data is synced, Finance and Operations apps show the preceding error message, because party record Party-001 of the Organization type already exists.

To fix the issue, change the automatic number sequence for the msdyn_partynumber field of the msdyn_party table in Dataverse to a different automatic number sequence.

Performance issue with customer or contact mappings

You might be able to marginally improve the performance of live synchronization for customers and contacts by customizing the getEntityDataSourceToFieldMapping method (in the CustCustomerV3Entity entity) method and the getEntityDataSourceToFieldMapping method (in the smmContactPersonCDSV2Entity entity). These customizations reduce the number of records in the BusinessEventsDefinition table. This reduction in the number of records, in turn, reduces the number of events that are raised.

The getEntityDataSourceToFieldMapping method in the CustCustomerV3Entity entity makes sure that an update of the customer's electronic address or postal address triggers business events, so that the updated data will be sent to Dataverse. If you don't use all the fields and don't need the information in dual-write, comment out the appropriate lines in the method. Every tracked field and table that is added in this method adds a record in the BusinessEventsDefinition table for the combination of the tracked field and tracked entity.

```csharp
public static container getEntityDataSourceToFieldMapping(container mapping)
{
    mapping += [
        [tablestr(DirPartyBaseEntity), tablenum(LogisticsPostalAddress), fieldstr(CustCustomerV3Entity, AddressRecordId)],
        [identifierstr(DirPartyBaseEntity), tablenum(LogisticsElectronicAddress), fieldstr(CustCustomerV3Entity, PrimaryContactURLRecordId)],
        [identifierstr(DirPartyBaseEntity1), tablenum(LogisticsElectronicAddress), fieldstr(CustCustomerV3Entity, PrimaryContactPhoneRecordId)],
        [identifierstr(DirPartyBaseEntity2), tablenum(LogisticsElectronicAddress), fieldstr(CustCustomerV3Entity, PrimaryContactEmailRecordId)],
        [identifierstr(DirPartyBaseEntity3), tablenum(LogisticsElectronicAddress), fieldstr(CustCustomerV3Entity, PrimaryContactFaxRecordId)],
        [identifierstr(DirPartyBaseEntity4), tablenum(DirPartyLocation), fieldstr(CustCustomerV3Entity, DirPartyLocationRecordId)],
        [identifierstr(DirPartyBaseEntity5), tablenum(LogisticsPostalAddress), fieldstr(CustCustomerV3Entity, InvoiceAddressRecordId)],
        [identifierstr(DirPartyBaseEntity6), tablenum(LogisticsPostalAddress), fieldstr(CustCustomerV3Entity, DeliveryAddressRecordId)],
        [identifierstr(DirPartyBaseEntity7), tablenum(DirPartyTable), fieldstr(CustCustomerV3Entity, PartyRecordId)]];
    return mapping;
}
```

In a similar manner, the getEntityDataSourceToFieldMapping method in the smmContactPersonCDSV2Entity entity makes sure that any update of the contact's electronic address or postal address triggers business events, so that the updated data will be sent to Dataverse. In the method, you can comment out the lines for any fields that you don't use.
public static container getEntityDataSourceToFieldMapping(container mapping)
{
    mapping += [
        [tablestr(DirPartyBaseEntity), tablenum(logisticsPostalAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryPostalAddressRecId)],
        [identifierStr(DirPartyBaseEntity), tablenum(DirPartyTable), fieldstr(smmContactPersonCDSV2Entity, PrimaryAddressLocation)],
        [identifierStr(DirPartyBaseEntity1), tablenum(LogisticsElectronicAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryContactEmailRecordId)],
        [identifierStr(DirPartyBaseEntity2), tablenum(LogisticsElectronicAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryContactFaxRecordId)],
        [identifierStr(DirPartyBaseEntity3), tablenum(LogisticsElectronicAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryContactPhoneRecordId)],
        [identifierStr(DirPartyBaseEntity4), tablenum(LogisticsElectronicAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryContactFacebookRecordId)],
        [identifierStr(DirPartyBaseEntity5), tablenum(LogisticsElectronicAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryContactTwitterRecordId)],
        [identifierStr(DirPartyBaseEntity6), tablenum(LogisticsElectronicAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryContactURLRecordId)],
        [identifierStr(DirPartyBaseEntity7), tablenum(LogisticsElectronicAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryContactLinkedInRecordId)],
        [identifierStr(DirPartyBaseEntity8), tablenum(LogisticsElectronicAddress),
            fieldstr(smmContactPersonCDSV2Entity, PrimaryContactTelexRecordId)],
        [identifierStr(DirPartyBaseEntity9), tablenum(DirPartyTable), fieldstr(smmContactPersonCDSV2Entity, PartyRecordId)]];
    return mapping;
}

After you update the methods, follow these steps.

1. Sync the database, and build the application.
2. Stop all the dual-write maps on the smmContactPersonCDSV2Entity and CustCustomerV3Entity entities.
3. Start the maps. You should see fewer records in the smmContactPersonCDSV2Entity and CustCustomerV3Entity entities and the BusinessEventsDefinition table, and performance might marginally improve.
This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues with the Dual-write module in Finance and Operations apps.

**IMPORTANT**

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

You can't load the dual-write module in a Finance and Operations app

If you can't open the Dual-write page by selecting the Dual Write tile in the Data management workspace, the data integration service is probably down. Create a support ticket to request a restart of the data integration service.

**Error when you try to create a new table map**

**Required credentials to fix the issue:** The same user that setup dual-write.

You might receive the following error message when you try to configure a new table for dual-write. The only user that can create a map is the user who setup the dual-write connection.

*Response status code does not indicate success: 401 (Unauthorized).*

**Error when you open the dual-write user interface**

You might receive the following error message when you try to access dual-write from the Data management workspace:

*login.microsoftonline.com refused to connect.*

To fix the issue, sign in by using an InPrivate window in Microsoft Edge, an incognito window in Chromium, or an incognito window in Google Chrome. You must also unblock or clear third-party cookies.

**Error when you link the environment for dual-write or add a new table mapping**

**Required role to fix the issue:** System administrator in both Finance and Operations apps and Dataverse.

You might encounter the following error when linking or creating maps:

*Response status code does not indicate success: 403 (tokenexchange).*

*Session ID: \{your session id\}*

*Root activity ID: \{your root activity\} id*
This error can occur if you don't have sufficient permissions to link dual-write or create maps. This error can also occur if the Dataverse environment was reset without unlinking dual-write. Any user with system administrator role in both Finance and Operations apps and Dataverse can link the environments. Only the user who setup the dual-write connection can add new table maps. After setup, any user with system administrator role can monitor the status and edit the mappings.

Error when you stop the table mapping

You might receive the following error message when you try to stop the table mappings:

```
[Forbidden], ["status":403,"source":null,"message":"Error from token exchange: User is not allowed to access connection dynamicscrmonline/xxxxxx-xxxx-xxxx-xxxxxxxx"], The remote server returned an error: (403) Forbidden.
```

This error occurs when the linked Dataverse environment isn't available.

To fix the issue, create a ticket for the Data Integration team. Attach the network trace so that the Data Integration team can mark the maps as Not running in the back end.

Errors while trying to start a table mapping

Unable to complete initial data sync

You might receive an error like the following when you try to run the initial data sync:

```
Unable to complete initial data sync. Error: dual-write failure - plugin registration failed: Unable to build dual-write lookup metadata. Error object reference not set to an instance of an object.
```

When you try to set that state of a mapping to Running, you might receive this error. The fix depends on the cause of the error:

- If the mapping has dependent mappings, then make sure to enable the dependent mappings of this table mapping.
- The mapping might be missing source or destination columns. If a column in the Finance and Operations app is missing, then follow the steps in the section Missing table columns issue on maps. If a column in Dataverse is missing, then click Refresh tables button on the mapping so that the columns are automatically populated back into the mapping.

Version mismatch error and upgrading dual-write solutions

You might receive the following error messages when you try to run the table mappings:

- Customer groups (msdyn_customergroups) : Dual write failure - Dynamics 365 for Sales solution 'Dynamics365Company' has version mismatch. Version: '2.0.2.10' Required version: '2.0.133'
- Dynamics 365 for Sales solution 'Dynamics365FinanceExtended' has version mismatch. Version: '1.0.0.0' Required version: '2.0.227'
- Dynamics 365 for Sales solution 'Dynamics365FinanceAndOperationsCommon' has version mismatch. Version: '1.0.0.0' Required version: '2.0.133'
- Dynamics 365 for Sales solution 'CurrencyExchangeRates' has version mismatch. Version: '1.0.0.0' Required version: '2.0.133'
- Dynamics 365 for Sales solution 'Dynamics365SupplyChainExtended' has version mismatch. Version: '1.0.0.0' Required version: '2.0.227'

To fix the issues, update the dual-write solutions in Dataverse. Make sure to upgrade to latest solution that matches the required solution version.
This topic provides troubleshooting information that can help you fix issues that are related to dual-write party and global address book functions.

**Verify these prerequisites**

Before you use the party and global address book functionality, make sure these are configured correctly.

- Integration keys.

<table>
<thead>
<tr>
<th>MAP</th>
<th>KEYS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account</td>
<td>accountnumber [Account Number]</td>
</tr>
<tr>
<td></td>
<td>msdyn_company.cdm_companycode [Company (Company Code)]</td>
</tr>
<tr>
<td>Contact</td>
<td>msdyn_contactpersonid [Account Number/Contact Person ID]</td>
</tr>
<tr>
<td></td>
<td>msdyn_company.cdm_companycode [Company (Company Code)]</td>
</tr>
<tr>
<td>Contact For Customer/Vendor</td>
<td>msdyn_contactforpartynumber [Contact For Party Number]</td>
</tr>
<tr>
<td></td>
<td>msdyn_associatedcompanyid.cdm_companycode [Associated Company (Company Code)]</td>
</tr>
<tr>
<td>Vendor</td>
<td>msdyn_vendoraccountnumber [Vendor Account Number]</td>
</tr>
<tr>
<td></td>
<td>msdyn_company.cdm_companycode [Company (Company Code)]</td>
</tr>
</tbody>
</table>

- Map versions. For more information, see [Party and global address book](#).

**Error about Location ID key when you try to add an address**

You might receive the following error message when you try to add an address to an account or contact in a Finance and Operations app or Microsoft Dataverse:

*Unable to write data to entity msdyn_partypostaladdresses. Writes to DirPartyPostalAddressLocationCDSEntity failed with error message Request failed with status code BadRequest and CDS error code: 0x80040265 response message: An error occurred in plugin. A record that has the attribute values Location ID already exists. The entity key Location ID Key requires that this set of attributes contains unique values. Select unique values and try again.*

To fix this issue, make sure that the key on the **Address** table is set as shown in the following table.

<table>
<thead>
<tr>
<th>PROPERTY</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Display Name</td>
<td>Location Key</td>
</tr>
</tbody>
</table>
If Dual-write Party and Global Address Book Solutions is not installed, then the key on this table is set to the `msdyn_locationid` field. Install the dual-write orchestration solution version (version 2.2.2.60 or later). This replaces the previous key created on `Address` table.

### Error when you try to run Customers, Vendors, or Contacts V2 maps

You might receive the following error message when you try to run Customers, Vendors, or Contacts V2 maps:

**Customers V3 (accounts): Project validation failed. Missing destination field**

*msdyn_billingaccount.accountnumber in the schema.* **Missing destination field**

*msdyn_primarycontact.msdyn_contactforpartynumber in the schema.*

There are multiple keys defined on the `msdyn_company` table in Dataverse. Dual-write cannot determine which key to use as integration key, and it randomly assigns one of the keys as integration key. To fix this issue, update the integration keys manually as described in step 8 of *Party and global address book*. Then refresh the table mappings. The missing destination field error should disappear.

### Error that the Party ID is different between Finance and Operations apps and Dataverse

You might receive an error message that the Party ID is different between a Finance and Operations app and Dataverse for the Customers, Vendors, or Contacts V2 maps.

To fix this issue, use the latest version of maps as described in step 7 of *Party and global address book*.

### Errors when upgrading Dual-write Party and Global Address Book Solutions

You might receive error messages when you upgrade Dual-write Party and Global Address Book Solutions from 2.4.0155 to later versions.

The party and global address book functionality was part of the dual-write orchestration solution when it was released for preview in January and February 2021. Based on customer feedback, the functionality was released for General Availability as a separate solution. As a separate solution, the functionality is optional. If you are using the preview version of the dual-write orchestration solution that contains party and global address book functionality, then you need to uninstall the dual-write orchestration solutions or reset the Dataverse environment and get the latest solutions.

Dual-write Party and Global Address Book Solutions contains the following solutions.

- **Party** - Includes the schemas for party, postal address, and electronic address.
- **Dynamics365GABExtended** - Includes all code and schema changes to support Accounts, Vendors, Contacts, and Contact for party functionality. This support was separated from the
Error when you try to create a new contact from the View Contact form

You might receive the following error message when you try to create a new contract from the View Contact form in a Finance and Operations app:

*Unable to write data to entity msdyn_contactforparties. Unable to lookup msdyn_parties with values (000006057). Unable to lookup cdm_workers with values (000020).*

To fix this issue, create the Contact record using the Add Contact form.

Error when you try to update a contact

You might receive the following error message when you try to update a contact that originated in Dataverse in a Finance and Operations app.

*Unable to write data to entity msdyn_contactforparties.Writes to smmContactPersonV2Entity failed with error message Request failed with status code BadRequest and CDS error code: 0x0 response message: An error occurred while validating input parameters: Microsoft.OData.ODataException: Cannot convert the literal ’’ to the expected type ‘Edm.Int32’.*

To fix this issue, install the latest Dual-write Party and Global Address Book Solutions. This issue is fixed in version 3.0.0.26.

Error when you create a new customer, vendor, or contact in Dataverse

You might receive the following error message when you try to create a new customer, vendor, or contact in Dataverse:

*Cannot update a party’s type from ‘DirOrganization’ to ‘DirPerson’, a delete of the existing party followed by an insert with the new type should be performed instead.*

This issue occurs in non-production environments if users try connecting one Finance and Operations app to different Dataverse organizations, or if they try to reset the existing Dataverse organizations. The issue is due to the number sequence for Party ID in the msdyn_party table in Dataverse. The follow sequence of events generates the error:

1. An account is created in Dataverse. Dataverse creates a new party with Party ID **Party-001** and Party type **Organization**.
2. The new account is then sent to the Finance and Operations app.
3. The Dataverse environment is reset later or the same Finance and Operations apps environment is again connected to a different Dataverse organization.
4. You create a new contact this time in Dataverse. The number sequence for msdyn_party starts with **Party-001**. This time, the party record is created with **Party-001** and Party type as **Person**.
5. The data is synced to the Finance and Operations app. Because the Finance and Operations app already has **Party-001** as **Organization**, the error is generated.

To fix this issue, change the auto number sequence for the msdyn_partynumber field in the msdyn_party table to a different auto number sequence.
Error when you run the initial sync of party postal addresses and party electronic addresses

You might receive an error such as "the Party number could not be found" when you try to run the initial sync of party postal addresses and party electronic addresses.

There is a range added to the DirPartyCDSEntity entity in Finance and Operations apps to filter only parties of type Person and Organization. As a result, the initial sync of the CDS Parties – msdyn_parties mapping will not sync parties of other types, including Legal Entity and Operating Unit. When the initial sync runs for CDS Party postal addresses (msdyn_partypostaladdresses) or Party Contacts V3 (msdyn_partyelectronicaddresses) you might see errors, for example, that the Party number could not be found in Dataverse.

We are working to remove the party type range on the Finance and Operations apps entity so that parties of all types synchronize to Dataverse successfully. Check back to this topic for updates.
This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues that are related to solution awareness.

**IMPORTANT**

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

**Error on the Dual-write page**

On the **Dual-write** page, you might receive an error message that resembles the following example:

*The entity with a name 'msdyn_dualwriteentitymap' with namemapping='Logical' was not found in the MetadataCache.*

To fix the issue, make sure that the dual-write core solution is installed in Dataverse. The dual-write core solution is a prerequisite for solution awareness.
This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it provides information that can help you fix issues that are related to upgrades of Finance and Operations apps.

**IMPORTANT**

Some of the issues that this topic addresses might require either the system admin role or Microsoft Azure Active Directory (Azure AD) tenant admin credentials. The section for each issue explains whether a specific role or credentials are required.

### Database synchronization errors

**Required role to fix the issue:** System admin

You might receive an error message that resembles the following example when you try to use the `DualWriteProjectConfiguration` table to update a Finance and Operations app to Platform update 30.

```
Infolog diagnostic message: 'Cannot select a row in Dual write project sync (DualWriteProjectConfiguration).
```

To fix the issue, follow these steps.

1. Sign in to the virtual machine (VM) for the Finance and Operations app.
2. Open Visual Studio as an admin, and open the Application Object Tree (AOT).
3. Search for `DualWriteProjectConfiguration`.
4. In the AOT, right-click `DualWriteProjectConfiguration`, and select **Add to new project**. Select **OK** to create the new project that uses default options.
5. In Solution Explorer, right-click **Project properties**, and set **Synchronize Database on Build** to **True**.
6. Build the project, and confirm that the build is successful.
7. On the **Dynamics 365** menu, select **Synchronize database**.
8. Select **Synchronize** to do a full database synchronization.
9. After the full database synchronization is successful, rerun the database synchronization step in Microsoft Dynamics Lifecycle Services (LCS) and use the manual upgrade scripts as applicable, so that you can proceed
Missing table columns issue on maps

**Required role to fix the issue:** System admin

On the **Dual-write** page, you might receive an error message that resembles the following example:

*Missing source field <field name> in the schema.*

<table>
<thead>
<tr>
<th>Source field</th>
<th>Map type</th>
<th>Destination field</th>
<th>Issues</th>
<th>Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td>✓</td>
<td>msdyn_productname [Product Name]</td>
<td>Missing source field msdyn_productname in the schema...</td>
<td>...</td>
</tr>
<tr>
<td>...</td>
<td>✓</td>
<td>msdyn_productnumber [Product Number]</td>
<td>Missing source field msdyn_productnumber in the schema...</td>
<td>...</td>
</tr>
</tbody>
</table>

To fix the issue, first follow these steps to make sure that the columns are in the table.

1. Sign in to the VM for the Finance and Operations app.
2. Go to **Workspaces > Data management**, select the **Framework parameters** tile, and then, on the **Table settings** tab, select **Refresh table list** to refresh the tables.
3. Go to **Workspaces > Data management**, select the **Data tables** tab, and make sure that the table is listed. If the table isn’t listed, sign in to the VM for the Finance and Operations app, and make sure the table is available.
4. Open the **Table mapping** page from the **Dual-write** page in the Finance and Operations app.
5. Select **Refresh table list** to automatically fill the columns in the table mappings.

If the issue still isn’t fixed, follow these steps.

**IMPORTANT**

These steps guide you through the process of deleting a table and then adding it again. To avoid issues, be sure to follow the steps exactly.

1. In the Finance and Operations app, go to **Workspaces > Data management**, and select the **Data tables** tile.
2. Find the table that is missing the attribute. Click **Modify target mapping** in the toolbar.
3. On the **Map staging to target** pane, click **Generate mapping**.
4. Open the **Table mapping** page from the **Dual-write** page in the Finance and Operations app.
5. If the attribute is not auto-populated on the map, add it manually by clicking **Add attribute** button and then clicking **Save**.
6. Select the map and click **Run**.
Verify dual-write configuration in Finance and Operations apps and Dataverse

This topic provides troubleshooting information for dual-write integration between Finance and Operations apps and Dataverse. Specifically, it explains how you can determine whether dual-write is configured in Finance and Operations apps and in Dataverse.

Verify that dual-write is configured in a Finance and Operations app

To determine whether the errors that you see when you try to save rows for update come from dual-write, first verify that dual-write is configured.

- If you have admin privileges in the Finance and Operations app, go to Workspaces > Data management, and select the Dual-write tile. If the details of the linked environments and the list of table maps that are running are shown, dual-write is configured.

<table>
<thead>
<tr>
<th>Table Map</th>
<th>Status</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sales tax groups (msdyn_taxgroups)</td>
<td>Running</td>
<td>1.0.0.0 - Dynamics 365</td>
</tr>
<tr>
<td>Job detail (cdm_jobs)</td>
<td>Mappings created, not running</td>
<td>1.0.0.0 - Dynamics 365</td>
</tr>
<tr>
<td>Employment (cdm_employments)</td>
<td>Running</td>
<td>1.0.0.0 - Dynamics 365</td>
</tr>
<tr>
<td>Fiscal calendar year integration entity (msdyn_fiscalcalendaryears)</td>
<td>Running</td>
<td>1.0.0.0 - Dynamics 365</td>
</tr>
</tbody>
</table>

- If you don't have admin privileges, you will receive an error message, *Unable to write data to entity <entity name>*. In the example in the following illustration, you can't create a customer row in the Finance and Operations app, because dual-write is configured, but the customer group and payment terms reference data don't exist in Dataverse.

![Unable to write data to entity accounts](image)

For information about how to fix issues when you create data in Finance and Operations apps, see Troubleshoot live synchronization issues.

Verify that dual-write is configured in Dataverse

When you create data, if you see the **Company** column on pages in Dataverse, dual-write is configured.
For information about how to fix issues when you create data in Dataverse, see Troubleshoot live synchronization issues.

For information about how to view error details if you encounter any errors while you create data in Dataverse, see Enable and view the plug-in trace log in Dataverse to view error details.
This topic describes error codes for the table map health check.

**Error 100**

The error message is, "Minimum required Finance and Operations platform version is PU 43 to run Finance and Operations recommendations."

The feature requires platform updates for version 10.0.19 or later of Finance and Operations apps.

**Error 400**

The error message is, "No business events registration data found for the entity {Finance and Operations UniqueEntityName} which means either the map is not running or all the field mapping are unidirectional."

**Error 500**

The error message is, "No project configurations found for project {project name}. This could be either the project is not enabled or all the field mappings are unidirectional from customer engagement to Finance and Operations."

Check the mappings for the table map. If they are unidirectional from customer engagement apps to Finance and Operations apps, no traffic is generated for live synchronization from Finance and Operations apps to Dataverse.

**Error 900**

The error message is, "Invalid source filter {sourceFilter} format for entity {Finance and Operations UniqueEntityName}."

The source filter that is specified on the table map for Finance and Operations apps isn't syntactically correct. To validate the filter criteria, see Troubleshoot live synchronization issues.

**Error 1000**

The error message is, "Entity {Finance and Operations UniqueEntityName} query used for dual-write live sync is {Finance and Operations EntityFilterQueryString}. Records which meet the query criteria will be picked up for live sync."

The entity query that was returned is the backing SQL query for the entity. Check for inner joins or filters on the query that determine the business data that is being picked up for live synchronization. Inner joins and filters are mandatory conditions that must be fulfilled for each record that is being picked up for dual-write live synchronization.

**Error 1300**

The error message is, "Virtual fields {s.EntityFieldName} for entity {Finance and Operations EntityMetadata.EntityProperties.LogicalEntityName} may not be tracked for dual-write."

Virtual fields from Finance and Operations tables aren't enabled for tracking. Live synchronization can sync the
data, but it won't be able to pick up the changes that are made on the columns.

**Error 1500**

The error message is, “There should be at least one field mapped to a non lookup field on customer engagement to enable tracking on the data source {datasource.DataSourceName}.”

The data source from the entity doesn't have any field that is mapped for dual-write. Changes to the underlying table won't be tracked for dual-write.

**Error 1600**

The error message is, “Datasource: {datasource.DataSourceName} for entity (Finance and Operations EntityMetadata.EntityProperties.LogicalEntityName) has a range. Only records that satisfy the range condition are picked up for outbound.”

Entities in Finance and Operations apps can have data sources where filter ranges are enabled. These ranges define the records that are picked up as part of live synchronization. If some records are skipped from Finance and Operations apps to Dataverse, check whether the records meet the range criteria on the entity. A simple way to do this check is to run a SQL query that resembles the following example.

```sql
select * from <EntityName> where <filter criteria for the records> on SQL.
```

**Error 1700**

The error message is, “Table: {datasourceTable.Key.subscribedTableName} for entity {datasourceTable.Key.entityName} is tracked for entity {origTableToEntityMaps.EntityName}. Same tables tracked for multiple entities can impact system performance for live sync transactions.”

If the same table is tracked by multiple entities, any change to the table will trigger dual-write evaluation for the linked entities. Although the filter clauses will send only the valid records, the evaluation might cause a performance issue if there are long-running queries or unoptimized query plans. This issue might not be avoidable from the business perspective. However, if there are many intersecting tables across multiple entities, you should consider simplifying the entity or checking optimizations for entity queries.
This topic lists frequently asked questions about dual-write and provides brief answers to help you quickly get the information that you require.

**Dual-write setup**

**Do you plan to enable dual-write to use Dataverse as a hub between multiple Finance and Operations environments?** If Dataverse is used as a hub, data can be synced between two or more Finance and Operations environments.

The current plan of row is to restrict dual-write to a one-to-one (1:1) mapping between a single Finance and Operations environment and a single Dataverse environment.

**Can I control the sequencing of maps in dual-write, as I can in Data integrator?**

Dual-write is transaction-based. For example, if a change in a Finance and Operations app triggers synchronization of multiple maps with Dataverse, by default, those changes will be sequenced in the order in which they are updated in the database. This pattern makes more sense in the context of initial synchronization. The system provides related table maps in a specified order, and you can reorder the list so that it best suits your environment.

**Do application users require any special permissions to enable or configure dual-write?**

You must have two Azure Active Directory (Azure AD) applications set up for the Finance and Operations environment and two application users set up in the Dataverse environment. These application users should contain the appropriate application IDs. For the connection to work properly, you must give the applications the relevant table permissions by using a security role. For more information, see [Verify requirements and grant access](#).

**Do end users require any special permissions to enable or configure dual-write?**

End users who are configuring dual-write mappings should have System Administrator security roles assigned in both Dataverse and Finance and Operations environments.

Dual-write mappings can be accessed by multiple users, as long as all the users and environments belong to a single tenant, and the user has the required security and licenses assignment.

**I have multiple legal entities. Some of my maps are legal table–specific or valid for only some of the legal entities. What is the best way to address this requirement? Can I apply a filter such as Company = USMF to address it?**

Legal table mapping can be done when the Dataverse environment is linked. You can't map table maps to a specific legal entity.

**If dual-write solutions are installed in Dataverse, can I uninstall them?**

Dual-write solutions are managed solutions that can be uninstalled. However, when a managed solution is uninstalled, all components in the solution are deleted. Any data that is stored in the components is also deleted. For more information, see [Maintain managed solutions](#).

**I have data in both a customer engagement app and a Finance and Operations app, and I bootstrap my existing data in the customer engagement app. If my data isn't currently aligned, can I specify a master source for the initialization run, so that all differences are applied to the target?**

After the bootstrapping is done, you can configure the initial synchronization to apply differences and select a master. For more information about bootstrapping, see [Bootstrap with company data FAQ](#). For more
Dual-write administration and management

**What is the purpose of the integration key, and is it mandatory?**

The integration key is the natural key that uniquely identifies rows. Integration keys are required only for Dataverse tables. You can manually create an integration key in dual-write. An integration key can also be automatically created from the table’s alternate keys, if an alternate key is already provided for the table. Integration keys are used for the same purpose as alternate keys: they provide an efficient and accurate way to integrate data with external systems. Integration keys are essential in cases where an external system doesn’t store the globally unique identifiers (GUIDs) that uniquely identify rows in Dataverse.

Dual-write uses integration keys to uniquely identify rows, by using one or more table column values that represent a unique combination. For example, to identify an account row by using an integration key, you can use the account number column. Alternatively, you can use the account number column together with other columns that have values that should not change. For more information, see Define alternate keys using Power Apps portal.

It's important that keys be matched between the Finance and Operations environment and the Dataverse environment. Otherwise, issues might occur during the initial synchronization phase.

**How do I move table maps between environments? Is version control supported for table maps?**

You can export maps and then import them into a different environment. You can automate the process by using Azure DevOps. You can have version control on your dual-write mappings, because the mappings are solution-aware components. For more information, see Update table maps and export them to other environments as a solution.

**Where can I find examples and patterns for filtering dual-write maps?**

For basic filtering examples, see Filter your data.

For more advanced examples for Dataverse, see Filter results. Nested lookup isn't supported in dual-write source filters. Only standard filter operators directly against table columns are supported.

For more advanced Finance and Operations filters, see Using Expressions in Query Ranges and Advanced filtering and query syntax.

**Dual-write live synchronization introduces tight coupling across applications. What happens if one side fails? Will the other side fail too?**

When the integration is in live sync mode, if the sync fails on one of the apps, then the other app will fail as well and users will receive an error. When the integration is paused, changes are staged. They are then written when the target system is up and running. For more information about how to automatically pause integrations, see Alert notifications.

When live synchronization is paused and then resumed, does it follow the sequence of changes? For example, if the Name column in the Finance and Operations app is changed from NameA to NameB to NameC, is customer engagement data changed from NameA to NameB to NameC, or is it changed directly from NameA to NameC?

The integration follows the complete sequence of changes. In the example, the customer engagement app data is changed from NameA to NameB to NameC.

**How do I handle a Finance and Operations database transfer from PROD to STAGE? What is the effect on dual-write? After the transfer, the systems are no longer in sync. Is the synchronization done automatically?**

Each linked environment-pair (Finance and Operations apps environment and Dataverse environment) should be treated as a single unit and refreshed accordingly. For example, if you are refreshing a sandbox from production, then both Finance and Operations app sandbox environment and the Dataverse sandbox environment should be refreshed from their production counterparts. If dual-write is already used in target
environments, those environments need to be unlinked. After the data refresh on target environments, these tables should be cleaned up:

- Finance and Operations apps tables: `DualWriteProjectConfiguration`, `DualWriteProjectFieldConfiguration`, and `BusinessEventsDefinition`.
- Dataverse tables: `DualwriteRuntimeConfiguration`.

The environments need to be relinked and maps reactivated manually.

I need real-time integration, and I want to move some tables or scenarios from Data integrator to dual-write. How do I migrate, and what are the implications of changing my integration pattern?

For information about how to migrate Prospect to cash to dual-write, see Migrating data from Data Integrator to Dual Write. In general, three things might change during migration:

- Manual migration of the maps from Data integrator to dual-write
- Table changes, because of the absence of advanced query capabilities
- Data migration, because of adaptation to new concepts such as company striping

On Finance and Operations data tables, can I develop unbounded columns that flow to Dataverse by using dual-write?

Yes. You can use both computed columns and virtual columns. However, you should monitor the performance overhead from the additional X++ logic that is required for reads and writes. Round-tripping within the same transaction isn’t allowed. Therefore, you should avoid using virtual columns to transform or calculate additional values through X++ and expect that to go back to Dataverse within the same transaction.

When I use the Dataverse offline app, what happens if I can’t sync the data after reconnection? Does this situation cause an inconsistent state between the Dataverse environment and the Finance and Operations environment?

You can interact with Dataverse data offline when using the Dynamics 365 for phones app or the Field Service Mobile app in offline mode. In both apps, data is stored offline and can be synced with the server at your discretion. If there are errors when the offline data is synced with the server, and updates can't be done because the other environment is failing, data sync will fail, and Dataverse will not be updated. When the integration is paused, you can re-run the sync and save your updates on the server. These changes will be staged and then synced with the Finance and Operations environment when the mapping is up and running again. For more information, see Run model-driven apps and canvas apps on Power Apps mobile.

Mapping concepts between apps

How are number sequences handled? For example, the customer account number is automatically generated in Finance and Operations apps, but it’s added manually in customer engagement apps.

Number sequences for Finance and Operations apps and customer engagement apps aren’t connected. In a scenario that involves a multi-mastered table, you must either plan for separate number sequence formats or create a range for each app. Here are some examples:

- In the Finance and Operations app, use `F0001`, `F0002`, `F0003`. In the customer engagement app, use `C0001`, `C0002`, `C0003`.
- In the Finance and Operations app, use `US0001` to `US4999`. In the customer engagement app, use `US5000` to `US9999`.

If a table is created in only one system, set up the number sequence in the source app only. For more information, see Autonumber columns.

Can I map a company-specific table in a customer engagement app with a global table in a Finance and Operations app, or a global table in a customer engagement app with a company-specific table in a Finance and Operations app?

Dual-write supports mappings only between cross-company tables or company-specific tables from both sides.
How do I make a company-specific table in Dataverse?

You can make Dataverse custom tables company-specific by adding a many-to-one (N:1) relationship between your custom tables and the out-of-box company table. You should also include the company foreign key as part of the table key. For more information, see [Company concept in Dataverse](#).

To enable table maps for dual-write, you must define an alternate key in Dataverse. The value of the alternative key in Dataverse must match the key that is defined in the Finance and Operations app. For more information, see [Criteria for linking tables](#).

Can I merge records in customer engagement apps while using dual-write?

No, Finance and Operations apps do not permit the merging of records. Because of this, the merge functionality in customer engagement apps will not execute when a dual-write mapping is present on a table.

Is there a document about best practices for table usage? Should I use Customers V2, Customers V3, or Customer Details? What is the difference between these tables, and what is the use case for each?

You should use the [out-of-box scenarios](#) if you can, because they cover common scenarios such as customer/vendor integration.
Virtual entities overview

11/24/2021 • 4 minutes to read • Edit Online

**IMPORTANT**

This functionality requires version 10.0.12 of Finance and Operations apps, and service update 189 of Microsoft Dataverse. The release information for Dataverse is published on the latest version availability page.

Virtual entities for Finance and Operations apps

Finance and Operations apps are a virtual data source in Dataverse, and enable full create, read, update, and delete (CRUD) operations from Dataverse and Microsoft Power Platform. By definition, the data for virtual entities doesn't reside in Dataverse. Instead, it continues to reside in the app where it belongs. Before CRUD operations can be performed on Finance and Operations entities from Dataverse, the entities must be made available as virtual entities in Dataverse. CRUD operations can then be performed from Dataverse and Microsoft Power Platform on data that resides in Finance and Operations apps.

All Open Data Protocol (OData) entities in Finance and Operations apps are available as virtual entities in Dataverse, and therefore also in Microsoft Power Platform. Makers can now use data directly from Finance and Operations apps to build experiences in customer engagement apps. These experiences offer full CRUD capability and don't require copying to Dataverse. Power Apps portals can be used to build external-facing websites that enable collaboration scenarios for business processes in Finance and Operations apps.

Virtual entities for core Human Resources

Core Human Resources entities can also be virtualized, just as Finance and Operations entities can. For more information, see Configure Dataverse virtual tables.

Architecture

Virtual entities are a Dataverse concept that is useful beyond Finance and Operations apps. The following illustration shows how the Finance and Operations provider for virtual entities is implemented. The provider implements six primary methods. The first five methods are the standard CRUD operations: Create, Update, Delete, Retrieve, and RetrieveMultiple. The last method, PerformAction, is used to call OData actions, as described later in this topic. Calls to the Finance and Operations virtual entity data provider (shown as “virtual entities plug-in” in the illustration) will cause a Secure Sockets Layer (SSL)/Transport Layer Security (TLS) 1.2 secure web call to the CDSVirtualEntityService web API endpoint of Finance and Operations apps. This web service then converts the queries into calls to the associated physical entities in Finance and Operations apps, and invokes CRUD or OData operations on those entities. Because a Finance and Operations entity is directly invoked in all operations, any business logic on the entity or its backing tables is also invoked.
During calls, there are two points of translation from Dataverse to Finance and Operations apps. The first point of translation occurs in the VE Plugin, which translates concepts such as entity physical names into Finance and Operations entity names. It also converts some well-known concepts, such as Company references. The web service call still uses the EntityCollection, Entity, and QueryExpression objects to express the operations that are performed, by using the translated entity names and concepts from the VE Plugin. Finally, the CDSVirtualEntityAdapterService web API in Finance and Operations apps completes the translation from QueryExpression to QueryBuildDataSource and other internal Finance and Operations language constructs.

All calls between Dataverse and Finance and Operations apps as part of virtual entities are done as service-to-service (S2S) calls, by using the Azure Active Directory (Azure AD) application that is specified in the configuration. The user of this application should have access only to the CDSVirtualEntityAdapterService web API and the catalog entity, CDSVirtualEntityListEntity. These privileges are included in the out-of-box security role that is named CDSVirtualEntityApplication. During the S2S calls, Dataverse provides the identity of the user in Dataverse who is invoking the action. The CDSVirtualEntityAdapterService web API looks up the associated user in Finance and Operations apps and runs the query in the context of that user. Therefore, the S2S call doesn’t have to have explicit access to all the Finance and Operations entities. Instead, it can rely on the privileges of the user who is invoking the action to determine data access.

**NOTE**

We always recommend that you have both Finance and Operations apps and Dataverse co-located in the same Azure region, to ensure optimal latency in virtual entity calls. When Finance and Operations apps and Dataverse are co-located, the virtual entity overhead is expected to be less than 30 milliseconds (ms) per call.

Power Apps Portal can also access virtual entities. Because Power Apps Portal authorization is based on contact records, a mapping between contact records and Finance and Operations users is maintained in the dyn_externalportalusermapping table in Dataverse. This table should be editable only by highly privileged users in Dataverse who have the rights to control the security access that portal users have to Finance and Operations virtual entities. Any Finance and Operations user who is set up for Power Apps portal access must have the CDSVirtualEntityAuthorizedPortalUser security role assigned, and can’t have the system administrator or security administrator role assigned. Regardless of the Power Apps portal security setting that is applied to virtual entities, the resulting query to Finance and Operations apps is always run as the associated Finance and Operations user, and is subject to that user’s entity and row security settings. Anonymous portal access is also supported. For information about this type of access and how it can be done, see Power Apps Portal reference.
The public entity name that is exposed in Dataverse metadata for the Finance and Operations virtual entity uses the physical name of the Finance and Operations entity. This could be different from the public name of the entity as exposed by the OData metadata in Finance and Operations apps.

Building an app requires capabilities to perform relational modeling between entities that are being used in the app. In the context of virtual entities, there will be scenarios where virtual entities and native entities in Dataverse must work together to enable the desired user experience. This topic explains concepts of relational modeling that can be implemented using virtual entities for Finance and Operations.

Generating virtual entities

By default, virtual entities for Finance and Operations apps don’t exist in Dataverse. A user must query the catalog entity to view the entities that are available in the linked instance of Finance and Operations. From the catalog, the user can select one or more entities, and then request that Dataverse generate the virtual entities. This procedure is explained in later sections.

Entity fields

When a virtual entity is generated for a Finance and Operations entity, the system tries to create each field in the Finance and Operations entity in the corresponding virtual entity in Dataverse. In an ideal case, the total number of fields will be the same in both entities, unless there is a mismatch in supported data types between Finance and Operations and Dataverse. For data types that are supported, the field properties in Dataverse are set based on the properties in Finance and Operations.

This rest of this section describes supported and unsupported data types. For more information about fields in Dataverse, see Fields overview.

<table>
<thead>
<tr>
<th>DATA TYPE IN FINANCE AND OPERATIONS</th>
<th>MODELED DATA TYPE IN DATaverse</th>
</tr>
</thead>
<tbody>
<tr>
<td>Real</td>
<td>Decimal</td>
</tr>
<tr>
<td></td>
<td>For information about the possible mismatch, see the next table.</td>
</tr>
<tr>
<td>Long</td>
<td>Decimal, where the precision equals 0 (zero)</td>
</tr>
<tr>
<td>Int</td>
<td>Integer</td>
</tr>
<tr>
<td>String (non-memo), String (memo)</td>
<td>String – single line of text, String – multiple lines of text</td>
</tr>
<tr>
<td>DATA TYPE IN FINANCE AND OPERATIONS</td>
<td>MODELED DATA TYPE IN DATaverse</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>UtcDateTime</td>
<td>DateTime (DateTimeFormat.DateTimeAndTime, DateTimeBehavior.TimeZoneIndependent)</td>
</tr>
<tr>
<td>An empty date (January 1, 1900) in Finance and Operations is surfaced as a null value in Dataverse.</td>
<td></td>
</tr>
<tr>
<td>Date</td>
<td>DateTime - (DateTimeFormat.DateTimeOnly, DateTimeBehavior.TimeZoneIndependent)</td>
</tr>
<tr>
<td>An empty date (January 1, 1900) in Finance and Operations is surfaced as an empty value in Dataverse.</td>
<td></td>
</tr>
<tr>
<td>Enum</td>
<td>Picklist</td>
</tr>
<tr>
<td>Finance and Operations enumerations (enums) are generated as global OptionSets in Dataverse. Matching between the systems is done by using the External Name property of values. Enum integer values in Dataverse aren't guaranteed to be stable between the systems. Therefore, you should not rely on them, especially in the case of extensible enums in Finance and Operations, because these enums don't have a stable ID either. OptionSet metadata is updated when an entity that uses the OptionSet is updated.</td>
<td></td>
</tr>
</tbody>
</table>

Fields of the real and long data types in Finance and Operations are modeled as the decimal data type in Dataverse. Because of the mismatch in precision and scale between the two data types, the following behavior must be considered.

<table>
<thead>
<tr>
<th>USE CASE</th>
<th>RESULTING BEHAVIOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dataverse has higher precision.</td>
<td>This use case should never occur unless the metadata is out of sync.</td>
</tr>
<tr>
<td>Finance and Operations has higher precision.</td>
<td>During a read operation, the value is rounded to the closest precision value in Dataverse. If the value is edited in Dataverse, it's rounded to the closest precision value in Finance and Operations. During a write operation, the value that is specified in Dataverse is written, because Finance and Operations supports higher precision.</td>
</tr>
<tr>
<td>Dataverse has higher scale.</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Finance and Operations has higher scale.</td>
<td>Dataverse shows the Finance and Operations value, even if it exceeds 100 billion. However, there will be a loss of precision. For example, 987,654,100,000,000,000 is shown in Dataverse as “987,654,099,999,999,900”. If the value of this field is edited in Dataverse, Dataverse validation throws an error that the value exceeds the maximum value before that value is sent to Finance and Operations.</td>
</tr>
</tbody>
</table>

The following data types in Finance and Operations aren’t supported in Dataverse. Fields of these data types in Finance and Operations entities won’t be made available in the corresponding virtual entities in Dataverse. If fields of these data types are used as parameters in Open Data Protocol (OData) actions, those actions won’t be available for use in the corresponding virtual entities. For more information about OData actions, see the OData actions section later in this topic.

- AnyType
Data types that are supported in Dataverse but not in Finance and Operations aren't supported in virtual entities for Finance and Operations.

**Entity key/primary key**

In Finance and Operations, entities can have one or more fields of various data types as the entity key. An entity key uniquely identifies a record in a Finance and Operations entity. Additionally, a record in an entity can be uniquely identified by a record ID primary key of the Int64 type.

In Dataverse, the primary key is always a globally unique identifier (GUID). The GUID-based primary key enables a record in an entity in Dataverse to be uniquely identified.

To bridge the implementation gap between Finance and Operations and Dataverse, the primary key of a virtual entity for Finance and Operations is a GUID (to comply with Dataverse). This GUID consists of the data entity ID in the first 4 bytes, and the record ID of the root data source in the entity as the last 8 bytes. This design satisfies Dataverse’s requirement that a GUID be used as the entity key. It also enables the table ID and record ID to be used to uniquely identify the entity record in Finance and Operations.

When using entities in Finance and Operations, you need to ensure that the root data source will always have a unique RecID. If this design is violated, duplicate GUID’s will show up in Dataverse for the corresponding virtual entity. Aggregate views are not supported via virtual entities for the same reason because these views may not have unique RecIDs.

**Primary field**

In Dataverse, each entity must have a primary field. This field must be a single field of the string type. The primary field is used in Dataverse in the following scenarios:

- The default views that are created for an entity include the primary field.
- The quick view form for an entity includes the primary field.
- A lookup to another entity is added to a page and shows the data from the primary field.

Based on this use of the primary field in Dataverse, the primary field for a virtual entity for Finance and Operations is designed to use the entity key of the corresponding entity in Finance and Operations.

Because the primary field in Dataverse is expected to have only one field of the string type, whereas the entity key in Finance and Operations can have multiple fields of various data types, the entity key fields are converted to strings. The strings are concatenated and separated by a pipe (|), to a maximum length of 255 characters. Any value that exceeds 255 is truncated. This virtual entity field that represents the primary field is named **mserp_primaryfield.**

**Relations**
Relations in Finance and Operations entities are modeled as one-to-many (1:n) or many-to-one (n:1) relations. These relations are modeled as relationships in the virtual entity in Dataverse. Note that many-to-many (n:n) relations aren’t supported in Finance and Operations.

For example, in Finance and Operations, if Entity A has a foreign key to Entity B, this relation will be modeled as an n:1 relationship in virtual entity Entity A in Dataverse. The schema name of this relationship in Dataverse uses the naming convention `mserp_FK_<source entity name>_<relation name>`. This naming convention has a maximum string length of 92 characters. Any relation where the schema name will produce a name that exceeds 92 characters won’t be generated in the virtual entity in Dataverse.

The external name of this relationship uses the naming convention `FK_<relation name>`. The external name is used to determine the relation in Finance and Operations when the query that is sent to Finance and Operations is built.

When a relationship is generated for a virtual entity in Dataverse, a new field of the lookup type is also added to the source entity. In the preceding example, when the relationship is created, a new lookup field that uses the naming convention `mserp_fk_<target_entity>_id` is added to source entity Entity A. Because there can be several relations in an entity in Finance and Operations, the same number of lookup fields (one per related entity) will be created in the source virtual entity. When this lookup field is added to a page or a view, it will show the primary field value from the related entity.

A relationship in the virtual entity in Dataverse will be generated only if the related entity in the relation already exists as a virtual entity in Dataverse. In the preceding example, if Entity B doesn’t exist as a virtual entity in Dataverse, the relation to Entity B won’t be created in Entity A when Entity A is generated as a virtual entity. This relation will be added to Entity A only when Entity B is generated as a virtual entity. Therefore, when a virtual entity is generated for Finance and Operations, validations are done to ensure that only relationships that can be complete and functional are generated in the virtual entity that is being generated.

In summary, a relationship to another Finance and Operations virtual entity might not exist in the virtual entity for either of the following reasons:

- The Finance and Operations entity that is participating in the relationship doesn’t exist as a virtual entity.
- The length of the name of the relationship exceeds 92 characters.

Note that if an error is encountered when any part of a Finance and Operations virtual entity is generated in Dataverse, the virtual entity won’t be created at all. If relationships don’t exist for either of the preceding reasons, the situation isn’t considered an error.

**Native entity–to–native entity relationships**

Native entity–to–native entity relationships are the standard Dataverse functionality, where relationships are resolved by using the GUID of the related entity. (This GUID is the entity key.) The GUID identifies the unique entity record in the related entity.

**Virtual table–to–virtual table relationships**

The relationships between two Finance and Operations virtual entities are driven by the relation metadata in the Finance and Operations entities. As was explained earlier, these relations are generated as relationships in Dataverse when the virtual entity is generated. As in the behavior for native entities in Dataverse, these relationships use the GUID to identify the unique record of the entity in Finance and Operations. Semantically, the GUID on the Finance and Operations virtual entity behaves like the GUID on the native Dataverse table. For information about the implementation of the GUID in Finance and Operations virtual entities, see the Entity
Virtual table–to–native table relationship

As was explained earlier, the GUID is the only information that is used to uniquely identify a record in a native Dataverse table (including in native entity–to–native entity relationships) or in a Finance and Operations virtual entity (including in virtual entity–to–virtual entity relationships). However, consider an example where you want to show sales orders from Finance and Operations for Account A in Dataverse. The query that is sent to Finance and Operations for this relationship will have a WHERE clause on the GUID of the entity key of the native accounts entity in Dataverse, because the sales orders must be filtered for a specific account in Dataverse. However, because Finance and Operations doesn’t have any information about the GUID of the entity in Dataverse, the query won’t return any sales orders. The query will be successful only if the WHERE clause has conditions that are based on the fields that Finance and Operations understands.

Therefore, how can the GUID of the accounts entity in Dataverse be replaced with fields that are in Finance and Operations, in such a way that the query that is sent to Finance and Operations will return the correct list of sales orders?

To solve this issue and enable a rich set of scenarios that allows for virtual entity–to–native entity relationships, relationships can be added to this type of entity. The relation will appear as a relationship when the virtual entity is synced.

In the above example, the relationship between the SalesOrderHeader virtual entity and the Account native entity should be based on the Account Number and Company fields. By default, the native account entity in Dataverse does not have a company field. For this example, we will add a company lookup field named new_testcompany to the native Account entity.

Next, we add a new key named new_accountcompanyidx, which specifies that (accountnumber, new_testcompany) together represent a unique row in the account entity in Dataverse.

The next step is to define this relationship in X++. The following example shows sample X++ code. The names of the fields, index, and mapping information should match the names of the fields and indexes created in Dataverse. In this example, a relationship named “synthaccount” will be created between the virtual SalesorderHeader entity and the native account entity in Dataverse. The mapped fields make up the new_accountcompanyidx index. The display name for the relationship will be @SYS11307. Note the backslash at the start of the display name. This ensures that the label defines the relationship, so that it is appropriately translated.

The field mapping indicates which field on the virtual entity maps to the field on the native entity. In the field mapping, the key is the virtual entity field, and the value is the native entity field.
The next step is to generate or refresh the virtual entity to get the new relationship. Note that relationships between a virtual entity and a native entity cannot be updated in Dataverse once it is created. The only way to make an update is to physically remove the relationship, refresh the entity, and then physically re-add the relationship in order to resolve the issue.

This relationship looks like a typical GUID-based relationship, but has extra metadata to translate query filters on the relationship into restrictions on the backing fields. The query that is now generated will have a WHERE clause that is based on the fields that Finance and Operations apps recognize. That query will then return the filtered list of sales orders, as expected.

Native entity–to–virtual entity relationships

Native entity–to–virtual entity relationships works much like native entity–to–native entity relationships. Users associate native records with virtual records in Finance and Operations, and the GUID of the virtual entity is saved on the native entity record. As was explained earlier, the entities that participate in a relationship will have the GUID field of the related entity on them. Therefore, when a quotation in Dataverse is associated with a customer in a Finance and Operations virtual entity, the GUID of the customer virtual entity will be saved in the quotation entity. This behavior enables records to be retrieved as expected, by using standard Dataverse functionality.

Enums

 Enums in Finance and Operations are modeled as OptionSets in Dataverse. When a virtual entity for Finance and Operations is generated, the required enums are generated as OptionSets. If an OptionSet already exists, it's used instead.

Company

An entity in Finance and Operations can be bound to a company, or it can be global. The virtual entity for a Finance and Operations entity that is bound to a company will have a relationship to the cdm_company entity in Dataverse. The cdm_company entity is a native entity in Dataverse and is part of the Dynamics365Company solution. As always, when a relationship is created, a lookup field is also created in the virtual entity for the related entity (cdm_company in this case). This lookup field is named Company, and it must be used to provide an optimal user experience where users can select a value in a list or go to the details of the related record. A field that is named Company Code is also added in the virtual entity. The value is a four-character string. This field must be used in programming.

Attachments

Attachments in Finance and Operations entities are supported on a per-entity basis. For example, an invoice header entity will implement an invoice-related attachments entity to enable attachments via entities.

Entities of this type will have relations with the corresponding attachments entity in Finance and Operations. Therefore, they will follow the same pattern as the other relations that were discussed earlier. In other words,
Finance and Operations entities that have implemented attachments functionality will also make attachments available by using virtual entities. Finance and Operations entities that don't support attachments also won't support attachments when they are virtualized in Dataverse.

Note that Finance and Operations virtual entities support only the reading of attachments. They don't currently support the creation, update, or deletion of attachments by using virtual entities.

**OData actions**

OData actions in the Finance and Operations entities are made available as custom actions in Dataverse. For more information about custom actions and what they enable in Dataverse, see [Custom actions](#).

Input and output parameters of the following types are supported. If an input or output parameter is of a different type, the OData action doesn't appear as the SDK message in Dataverse.

- Integer
- String
- Guid
- Boolean
- Date/Datetime

Here are some examples of OData actions that are supported in Finance and Operations entities, but that aren't supported in the corresponding virtual entities in Dataverse:

- RetailStoreTenderTypeTable.queryDistinctTenderTypeIdAndName (a collection of RetailStoreTenderTypeTable entity)
- DocumentRoutingClientApp.syncPrinters (DocumentRoutingClientApp entity)
- DocumentRoutingClientApp.updateJobStatus (DocumentRoutingJobStatus enum)
- DimensionCombination.getCombinationDisplayValue (LedgerJournalACType enum)

**Labels and localization**

Labels that are defined on metadata, such as entity names and field names in Finance and Operations, are retrieved when virtual entities are generated in Dataverse. The labels are retrieved by passing the list of language locales that are installed in Dataverse. Finance and Operations returns each label as a list of locale/value sets that are then used to construct a label instance in Dataverse. Only the language packs that exist at the time of entity generation or update are included. Additionally, only labels that Finance and Operations has provided a translation for are included. Any missing translations revert to the label ID, such as @SYS:DataEntity. After a new language pack is installed in Dataverse, existing entities must be updated to pick up the new label information, if labels in that language exist in Finance and Operations.

Any runtime labels are returned in the language of the current user context. In other words, they are returned in the language that is specified on that user's UserInfo record in Finance and Operations. This behavior also applies to error messages.

**Error handling**

Finance and Operations create, read, update, and delete (CRUD) business logic on entities and backing tables is run when it's called through the virtual entity in Dataverse. If any exception is thrown on the Finance and Operations side, the last message in the error log is returned to Dataverse and is thrown as an InvalidPluginExecutionException exception that contains the message from Finance and Operations. Because the Finance and Operations code runs in the context of the user, the language of the error message is based on the language that is specified on the UserInfo record in Finance and Operations. If any messages that are written to the info log in Finance and Operations don't result in an exception, they aren't shown in Dataverse.
Calculated/unmapped fields

Calculated and unmapped fields in Finance and Operations entities are also available in the corresponding virtual entities in Dataverse.
The application lifecycle for an end-to-end solution using Finance and Operations virtual entities will encompass both Finance and Operations as well as Dataverse. This topic explains this in detail.

Solution management

Virtual entities for Finance and Operations don't exist in Dataverse until they are created. Virtual entities must be created inside a solution. The MicrosoftOperationsERPVE solution is used for this purpose. This solution will contain all the virtual entities that are created from an instance of Finance and Operations.

MicrosoftOperationsERPVE is a managed solution. By definition, a managed solution can't be modified after it has been generated. However, MicrosoftOperationsERPVE is a managed solution that grants privileges to update the components (that is, virtual entities) that are inside it. Therefore, new virtual entities can be added to the solution as they are created, and existing virtual entities can be updated as required. Nevertheless, the privileges to modify the managed solution are available only to the platform itself. Users can't make changes directly to the solution.

Because MicrosoftOperationsERPVE is a managed solution, solutions from customers, partners, and independent software vendors (ISVs) can take a dependency on it. This capability allows for consistent application lifecycle management (ALM) for solutions that use and depend on the virtual entities for Finance and Operations.

When a solution that depends on MicrosoftOperationsERPVE is exported, placeholders for the virtual entities that are used in the solution are added in the exported solution. When that solution is imported into another Dataverse environment, the import process also generates the dependent Finance and Operations virtual entities in the MicrosoftOperationsERPVE solution for the Finance and Operations instance that is connected to the Dataverse environment. Therefore, MicrosoftOperationsERPVE must already exist before a solution that depends on it is imported. Otherwise, an error message is shown. Additionally, if a dependent entity isn't available in the Finance and Operations instance, the virtual entity for that entity won't be generated. Virtual entities are generated only for entities that are available.

NOTE

If a virtual entity already exists in Dataverse and a solution is being imported that now references new fields in the virtual entity which does not exist in Dataverse, a manual refresh must be performed on the virtual entity to get the latest metadata from Finance and Operations.

The following list describes other solutions that Finance and Operations virtual entities require to work, and that must be available in the Dataverse environment:

- MicrosoftOperationsERPCatalog – This solution provides a catalog of the available entities in a Finance
and Operations instance. It also provides the connection that is used to set up a configuration. For more information, see the later sections of this topic.

- **MicrosoftOperationsVESupport** – This solution provides the virtual entity provider for Finance and Operations apps. The provider can communicate with Finance and Operations apps and Dataverse. For more information, see the next section.

- **Dynamics365Company** – This solution adds the Company entity, which is referenced by all Finance and Operations entities that have a `PrimaryCompanyContext` metadata value.

All these solutions must be present in an environment. Otherwise, virtual entities won't work with Finance and Operations apps. These solutions are packaged together to allow for easier portability across environments.

## Managing entities from multiple environments

The MicrosoftOperationsVESSupport solution consists of the `msdyn_financeandoperationsvirtualentity` entity. This entity represents the virtual entity data source for Finance and Operations that captures connection setup information. Each record in this entity represents a connection to a Finance and Operations instance.

A catalog is used to list all the entities in a Finance and Operations instance that are available for virtualization in Dataverse (in other words, all the entities in Finance and Operations that are enabled for Open Data Protocol [OData]). The catalog is part of the default MicrosoftOperationsERPCatalog solution and is applicable to a Finance and Operations instance.

Note that each Dataverse environment must point to only one Finance and Operations instance at any time, and each Finance and Operations environment must point to only one Dataverse environment. Therefore, there should be only one record in the `msdyn_financeandoperationsvirtualentity` entity.

The `mserp_financeandoperationsentity` entity that represents the catalog can be queried to list the entities in a Finance and Operations instance. Because this entity is a virtual entity, the catalog is never persisted in Dataverse.

Notice that the name of the catalog entity has the "mserp_" prefix. This prefix identifies the entities in the catalog as Finance and Operations entities. The same prefix is also added to the system names of the virtual entities that are generated for Finance and Operations in the MicrosoftOperationsERPVE solution. Therefore, the maker can distinguish Finance and Operations virtual entities from other entities. The prefix is set in the managed solution and can't be changed.

## Managing entities from multiple ISV solutions

One or more ISV solutions will take a dependency on the MicrosoftOperationsERPVE solution to use virtual entities for Finance and Operations. Because custom entities in Finance and Operations use the same catalog as out-of-box entities in Finance and Operations, the virtual entities for custom Finance and Operations entities will also be generated in the MicrosoftOperationsERPVE solution.

The established guidelines and ALM for entity development in Finance and Operations ensure that there are no conflicting entity names across ISV solutions. Therefore, no conflicts of this type can occur when virtual entities are generated in Dataverse for custom Finance and Operations entities from multiple ISV solutions. All virtual entities for Finance and Operations entities, including custom entities, will have the "mserp_" prefix that was mentioned earlier.

## Managing a Finance and Operation instance in a Dataverse environment for virtual entities

One Finance and Operations instance must be linked to a Dataverse environment for virtual entities. The connection setup information that is required is captured in a virtual entity data source for Finance and Operations. This data source is included in the MicrosoftOperationsERPCatalog solution.
This topic explains how to configure virtual entities for Finance and Operations apps in Microsoft Dataverse.

**IMPORTANT**

The configuration steps in this topic are required only for Finance and Operations apps environments for which the Microsoft Power Platform integration is *not* enabled. For Finance and Operations apps environments for which the Microsoft Power Platform integration is enabled, the virtual entity configuration that is outlined in this topic is automatically done as part of the process for enabling the integration. For more information about how to enable the Microsoft Power Platform integration for Finance and Operations apps environments, see [Enable the Microsoft Power Platform integration](#).

The Dataverse solution for Finance and Operations virtual entities must be installed from Microsoft AppSource. For more information, see [Finance and Operations virtual entity](#).

Ensure the following solutions are installed in Dataverse.

- **Dynamics365Company** - This adds the Company entity, which is referenced by all Finance and Operations entities with a PrimaryCompanyContext metadata value.
- **MicrosoftOperationsVESupport** - This provides the core support for the Finance and Operations virtual entity feature.
- **MicrosoftOperationsERPCatalog** - This provides a list of available Finance and Operations entities through the mserp_financeandoperationsentity virtual entity.
- **MicrosoftOperationsERPVE** - This is the API-managed solution, which will contain the generated virtual entities as they are made visible.

When updates are available for the virtual entity solution, they can be manually applied in the Power Platform admin center. For more information about how to manually install and update the virtual entity solution, see [Manage Dynamics 365 apps](#).

**NOTE**

For Finance and Operations apps environments that the Microsoft Power Platform integration is enabled for, available updates to the virtual entity solution are automatically applied.

**Authentication and authorization**

After the solutions are imported into the Dataverse environment, both environments must be set up to connect to each other. Dataverse will call Finance and Operations apps by using Service-to-Service (S2S) authentication, based on an Azure Active Directory (Azure AD) application. This new Azure AD application represents the single instance of the Dataverse environment. If you have multiple pairs of Dataverse and Finance and Operations apps environments, separate Azure AD applications must be created for each pair to ensure that connections are established between the correct pair of Finance and Operations apps and Microsoft Power Platform environments.
Register the app in the Azure portal
The following procedure explains how to create the Azure AD application.

**IMPORTANT**
The Azure AD application must be created on the same tenant as the Finance and Operations apps.

2. Select New Registration. Enter the following information:
   - **Name** - Enter a unique name.
   - **Account type** - Enter *Any Azure AD directory* (single or multi-tenant).
   - **Redirect URI** - Leave blank.
   - Select Register.
   - Make a note of the Application (client) ID value, because you will need it later.
3. Create a symmetric key for the application.
   - Select Certificates & secrets in the newly created application.
   - Select New client secret.
   - Provide a description and an expiration date.
   - Select Save. A key will be created and displayed. Copy this value for later use.

Grant app permissions in Finance and Operations apps
The Azure AD application that you created will be used by Dataverse to call Finance and Operations apps. Therefore, it must be trusted by Finance and Operations apps and associated with a user account that has the appropriate rights. A special service user that has rights only to the virtual entity functionality must be created in Finance and Operations apps. This service user must have no other rights. After you complete this step, any application that has the secret of the Azure AD application that you created will be able to call this Finance and Operations apps environment and access the virtual entity functionality.

1. In Finance and Operations, go to System Administration > Users > Users.
2. Select New to add a new user. Enter the following information:
   - **User ID** - Enter dataverseintegration (or a different value).
   - **User name** - Enter dataverse integration (or a different value).
   - **Provider** - Set to NonAAD.
   - **Email** - Enter dataverseintegration (or a different value, does not need to be a valid email account).
   - Assign the security role CDS virtual entity application to this user.
   - Remove all other roles including System user.
3. Go to System Administration > Setup > Azure Active Directory applications to register Dataverse.
   - Add a new row.
   - **Client ID** - The Application (client) ID created above
Configure the virtual entity data source

The next step in the process is to provide Dataverse with the Finance and Operations instance to connect to. The following steps walk through this part of the process.

1. In Dataverse, go to Advanced Settings > Administration > Virtual Entity Data Sources.
2. Select the data source named “Finance and Operations”.
3. Fill in the information from the steps above.
   - **Target URL** - The URL at which you can access Finance and Operations.
   - **OAuth URL** - https://login.windows.net/
   - **Tenant ID** - Your tenant, such as “contoso.com”.
   - **AAD Application ID** - The Application (client) ID created above.
   - **AAD Application Secret** - The secret generated above.
   - **AAD Resource** - Enter 00000015-0000-0000-c000-000000000000 (this is the Azure AD application representing Finance and Operations, and should always be this same value).
4. Save the changes.

When the virtual entity configuration is completed, you can enable the virtual entities in Dataverse. For more information, see Enable Microsoft Dataverse virtual entities.
Because many entities that are available in Finance and Operations apps are enabled for Open Data Protocol (OData), the entities aren’t available as virtual entities in Microsoft Dataverse by default. After configuration is completed for Finance and Operations apps virtual entities in Dataverse, the virtual entities can be enabled in the Dataverse environment. Administrators can then determine which entities will be exposed as virtual entities that can be used in Dataverse.

**NOTE**
Configuration of Finance and Operations apps virtual entities in Dataverse is a prerequisite for enabling the virtual entities. The configuration is automatically done for Finance and Operations apps environments that are linked to a Microsoft Power Platform environment. For unlinked environments, manual configuration must be completed before the virtual entities can be enabled. For step-by-step information about how to configure Finance and Operations apps virtual entities in Dataverse, see Configure Dataverse virtual entities.

Generate virtual entities

1. In Dataverse, select the **Advanced find** filter button.

2. Search for **Available Finance and Operations Entities**, and select **Results**.

3. Find and open the entity that you want to enable.

4. Select the **Visible** checkbox, and then save your change.
The virtual entity is generated and will appear on all the appropriate menus. For example, it will appear in the **Advanced find** dialog box.

**Refresh virtual entity metadata**

You can force a refresh of a virtual entity’s metadata when you expect that the entity metadata in Finance and Operations apps has changed. To force a refresh, select the **Refresh** checkbox, and then save your change. The **latest entity definition from Finance and Operations apps is synchronized to Dataverse,** and the virtual entity is updated.

**Reference virtual entities**

All virtual entities are generated in the **MicrosoftOperationsERPVE** solution, which is API managed. Items in the solution change as you make entities visible or hidden. Nevertheless, the solution is still a managed solution that you can take dependencies on.

The standard Application Lifecycle Management (ALM) flow is to take a standard reference to a virtual entity from this solution. You can do this by using the **Add existing** action in the independent software vendor (ISV) solution. The virtual entity will be shown as a missing dependency of the solution, and it will be checked when the solution is imported. During import, if a specified virtual entity doesn't exist, it's automatically made visible. No additional work is required.

Follow these steps to consume virtual entities:

1. In Dataverse, follow the usual steps to create a separate solution that contains the consuming logic. See **Create a solution** in the Power Platform documentation for additional information on creating a solution.
2. Select **Add existing > Table**.
3. In the **Add existing tables** list, select the virtual entity that you want to reference.

4. When you're prompted to select assets to add, select any forms, views, or other elements that you want to customize, and then select **Finish**.

You can use the development tools to modify existing elements for the virtual entity, such as forms. You can also add new forms, views, and other elements.

When the solution is exported, it will contain hard dependencies on the virtual entity that is generated in the **MicrosoftOperationsERPVE** solution.
Power Apps portals will enable create, update, and delete (CRUD) operations to Finance and Operations entities that are available as virtual entities in Dataverse. This topic explains the scenarios that are implemented in Power Apps portals for Finance and Operations apps.

Anonymous access from Power Apps portals

Collaboration scenarios in business processes such as bidding or onboarding of prospects in Finance and Operations require that external users participate from the Power Apps portal, even though they aren't users in Finance and Operations apps. The simplicity of anonymous access is appealing in these types of scenarios because the users, who might not be Finance and Operations apps users, don't have to sign in. However, they are expected to perform CRUD operations in Finance and Operations to complete any meaningful tasks in the business processes.

To ensure that only the required entities are enabled for anonymous access, a user in Finance and Operations must be designated as the user who is used for anonymous access. This designation is configured in the Anonymous portal access user ID field on the Virtual entity tab on the System parameters page (System administration > System parameters). The designated user can then be assigned to duties and security roles to control access to specific data that must be made available to all users who will interact anonymously from the Power Portal.

Note that because this scenario involves anonymous access, the only user context that matters, from a security perspective, is the user who is designated in the Anonymous portal access user ID field.

Authenticated access from Power Apps portals

Fully authenticated user access from Power Apps portals to Finance and Operations lets users in Finance and Operations also interact from Power Apps portals. A user who signs in to the Power Apps portal is also a known user in Finance and Operations who has appropriate security roles based on job requirements. These roles govern the security access to data for the authenticated user in Power Portal. In addition, any Finance and Operations user that is expected to also use Power Apps portal to access Finance and Operations data must also belong to the CDSVirtualEntityAuthenticatedPortalUser security role. This provides an additional layer of security and also provides a way to know the total users that are authorized to access from Power Apps portals.

Because Power Apps portals authentication is linked to the Contacts entity in Dataverse, a mapping must be established between the Dataverse contact and the corresponding user in Finance and Operations. This mapping can be done by adding entries to the msdyn_externalportalusermapping entity. From a security perspective, the scope of virtual entities that are made available to authenticated users must be configured as Global in the Power Apps portal.

When authenticated users from a different tenant need to be added to Finance and Operations as users, you must use the Create new user process in Finance and Operations. This process adds cross-tenant users as Microsoft Azure Active Directory (Azure AD) business-to-business (B2B) guest users.
NOTE
Access from the Power Apps Portal will fail if the user (authenticated or anonymous) has been assigned the System administrator role in any Finance and Operations apps.
This topic is a collection of frequently asked questions about Finance and Operations virtual entities.

Do Tier 1 Finance and Operations environments or demo topologies work?
Yes, Tier 1 and DEVTEST and DEMO topologies should work.

What version of Finance and Operations do I need?
10.0.12 is the minimum version that is required.

Can a solution from an independent software vendor (ISV) take a dependency on virtual entities? What does the application lifecycle management (ALM) look like?
Yes. The virtual entities are all generated in the MicrosoftOperationsERPVE solution, which is API-managed. In other words, the items in the solution change as you make entities visible or hidden, but the solution is still a managed solution that you can take dependency on. The standard ALM flow just takes a standard reference to a virtual entity from this solution with the Add existing option in the ISV solution. Missing dependency of the solution will be checked when the solution is imported and during import, if a specified virtual entity doesn’t yet exist, the virtual entity is automatically made visible.

Which entities from Finance and Operations do users see in the catalog in Dataverse?
Generally, users see all entities where IsPublic is set to Yes. These entities are the same entities that are currently visible in Open Data Protocol (OData).

Do all Microsoft Power Platform users have to be users in Finance and Operations?
Any interactive user of Microsoft Power Platform who tries to access Finance and Operations data through a virtual entity must also exist as a user in Finance and Operations. Therefore, technically, not all users have to be users in Finance and Operations. Only those users who access Finance and Operations data through virtual entities must be users in Finance and Operations.

A S2S application user can also be used to call into virtual entities. For this kind of integration, the application user must be set up in System administration > Setup > Configure Azure Active Directory Applications. This allows for applications to integrate with Finance and Operations using virtual entities.

Where do I find the catalog entity?
In the Advanced find window, the entity is named Available Finance and Operations Entities.

Is there a way to specify a company when I perform data operations on a virtual entity?
Yes. Although the company is implicit in Finance and Operations, it's an explicit field on each company-striped entity in Dataverse. You can use either the Company Code field, where the value is a four-character string, or the Company field, which is a lookup to cdm_Company. Both approaches provide the same information.

Can I change the prefix for the virtual entities?
No. All Finance and Operations virtual entities should be generated in the MicrosoftOperationsERPVE solution, and they should all have the "mserp_" prefix. This prefix should not be changed. If you have a scenario where
you believe the prefix has to be changed, you should share that scenario with Microsoft.

**How can I filter data in an app that is created by using Power Apps, based on the current user or any other dynamic criteria, such as today-10?**

You can write a pre-operation plug-in on the RetrieveMultiple message of the entity and change the criteria on the query in it. Alternatively, you can write a post-operation plug-in to filter the results before they are returned.

**Can I pin a model-driven app into Finance and Operations?**

No, it isn’t currently possible to pin a model-driven app into Finance and Operations.

**How can I show, in the same grid, data from multiple virtual entities that are joined to a physical entity record in Dataverse?**

This approach isn’t currently possible in Dataverse.

**How do I add subcomponents in the new Power Apps experience?**

As in the previous Power Apps user interface (UI), you must redo the **Add Existing** operation. After the solution is selected, and Customer Groups has already been added as an entity, follow these steps.

1. Select **Add existing** > **Entity**.
2. Select customer group entity, and then select **Next**.
3. Under **Components**, select **Select components**.
4. Select the fields, relationships, and forms that you want, and then select **Add**.

**If I want a default value to be entered in a field during pre-create, will an initValue on the data entity work?**

Yes. Here is the order of calls:

1. Dataverse sends a create or update message.
2. All the existing logic on the Finance and Operations entity and backing tables is invoked. This logic includes default value entry that might change values.
3. Dataverse sends another Retrieve (single) message to get the latest copy of the data, including any fields that default values were entered for.

**Can I debug Finance and Operations when we do a create, read, update, and delete (CRUD) operation from Dataverse? If so, which process do I have to attach?**

Yes, to debug in Finance and Operations, open Visual Studio as an admin. Typically, Finance and Operations apps run under w3wp.exe as a process. However, when you open Visual Studio as an admin, IISExpress.exe is automatically opened, and Finance and Operations is hosted there. You can attach to IISExpress.exe (or to w3wp.exe if not running Visual Studio as an admin). To set breakpoints in the virtual entity code, find the **CDSVirtualEntityAdapter** and **CDSVirtualEntityController** classes. The adapter class is the first class that is called, and it only does serialization/deserialization. It then delegates to the controller class to do the actual queries. Therefore, the controller class is usually the easiest place to put breakpoints.

**Does the form business logic in Finance and Operations get called through virtual entities?**

Finance and Operations business logic that resides on forms isn’t invoked through virtual entities. Instead, you should expect the same behavior that you get through OData access to the same entities. The expectation is that an entity that is exposed to OData (that is, **IsPublic** is set to **Yes**) has appropriate protections to ensure that data can’t be corrupted. If any entity lacks this protection, that situation represents a bug in the entity. If you see differences in entity behavior between OData and virtual entities, that situation represents a bug in the virtual entity feature.

**If I develop a new Finance and Operations entity and want to see it in Dataverse, do I have to select Refresh entity list in Finance and Operations? Do I have to do anything in Dataverse?**

In theory, no, you don’t have to refresh the entity list. At most, you might have to either reset Internet Information Services (IIS) or restart IIS Express, depending on where Application Object Server (AOS) is running. The fact that the list of entities is accurate is cached in SysGlobalObjectCache, which is a per-process cache. Any
time that this cache doesn't indicate that the list is accurate, the list is rebuilt. The rebuild process takes about five seconds. Therefore, when you restart your AOS process (w3wp.exe or iisexpress.exe), the list will be accurate the next time that you query it from Dataverse. Additionally, although recompilation should flush the SysGlobalObjectCache cache, it might not. In that case, an AOS restart will flush it.

**Is there guidance on when to use a virtual entity and when to use dual-write?**

Guidance on when to use a virtual entity and when to use dual-write is covered in Integration between Finance and Operations apps and third-party services.

**When adding records using virtual entities is there any way to use number sequences?**

Yes, if the Finance and Operations entity can auto generate number sequences, then it will work the same way from the virtual entity.

**Why does ‘search view’ not work in Power Apps?**

If there are no fields added in the quick find view for the entity, then the search box does nothing. The workaround is to add one or more fields of the entity to the quick find view.

**The virtual entity performance is slow when a virtual entity has relationships to other entities. Is there guidance on how to avoid these issues?**

There could be several reasons why performance is slow when a virtual entity has relationships to other entities. This section will be updated as new patterns are identified. The following is currently known patterns, which can be used as a guidance.

When virtual entities have relationships to other entities, the virtual entity framework needs to query the related entities if the field select list includes the foreign key values for the related entities. By default, queries against the entities return all fields unless the caller requests a specific set of fields. The best practice is to specify a narrow select list. This can help to prevent slow performance.

An example of this issue is explained in Optimize Dataverse virtual table queries.
Business events provide a mechanism that lets external systems receive notifications from Finance and Operations applications. In this way, the systems can perform business actions in response to the business events.

Business events occur when a business process is run. During a business process, users who participate in it perform business actions to complete the tasks that make up the business process.

A business action that a user performs can be either a workflow action or a non-workflow action. Approval of a purchase requisition is an example of a workflow action, whereas confirmation of a purchase order is an example of a non-workflow action. Both types of actions can generate business events that external systems can use in integration and notification scenarios.

**Prerequisites**

Business events can be consumed using Microsoft Power Automate and Azure messaging services. Therefore, customers must bring their subscriptions to such assets to use business events.

**IMPORTANT**

Business events must not be considered a mechanism for exporting data. By definition, business events are supposed to be lightweight and nimble. They aren't intended to carry large payloads to fulfill data export scenarios.

**Business events that are implemented**

Business events are implemented in some business processes out of the box. These business events include both workflow and non-workflow business events. For more information, see Application business events, Workflow business events, and Alerts as business events.

A developer must use extensions to implement new business events. For more information, see Business events developer documentation.

**Business event catalog**

The business events catalog can be accessed from System administration > Set up > Business events. The business event catalog lists the business events that are available in the instance that you're using. The catalog is useful because it shows which business events are available, and you can filter it by category, business event ID, and name.

The category of a business event identifies its source. Business events that originate from the workflow system are assigned to the Workflow category. For business events that originate from other modules, the module name is used as the category name.

The business event catalog is built during database synchronization at the time of deployment. Therefore, users should see the complete list of business events in the catalog. However, if an explicit update of the catalog is required, you can select Manage > Rebuild business events catalog.
For each business event, the business event catalog shows a description. This description can help you better understand the business event and its context in the business process. The catalog also shows the list of data fields that will be sent out in the event.

In scenarios where external integration systems require the schema of the payload for a business event during development, you can select **Download schema** to download the JavaScript Object Notation (JSON) schema.

In summary, the business event catalog helps identify the business events that are required for an implementation. It also helps identify the schema for each business event.

The next step is to manage the endpoints.

**Business events parameters and processing**

The application allocates dedicated batch threads to process business events in near real time. The maximum number of threads cannot exceed the total threads available in the system (**System administration > Server configuration**). Because threads are a shared resource for all batch processing, care must be taken when deciding to change the thread allocation for business events. The total threads allocated for business events is controlled using a parameter in the business events parameter table. This setting is not exposed from the user interface (UI), so a support case must be created to get this count changed in production environments as this will need database access.

---

**IMPORTANT**

There may be reliability issues with dedicated batch threads. Microsoft is working to resolve this issue and as a result, we recommend that you schedule the manual batch job to process business events, as explained below. We will update this topic when this issue is resolved.

---

The business events batch processing job is available as a workaround to mitigate issues with the dedicated processing, if needed. The batch job can be enabled and scheduled from the **Business events parameters** page.

In the event of an error while sending business events to its end point, the system retries to send the business events three times with an interval of one second per retry. This is the default setting that can be changed on the **Business events parameters** page.

The number of endpoints that can subscribe to the same business event in a legal entity is limited to ten by default. This can be changed on the **Business events parameters** page.
The out-of-the-box default settings for the above described parameters can be restored on the Business events parameters page.

Activating business events

Business events in the business event catalog aren’t active by default. From the catalog, you can activate any business events that you require. Select one or more business events, and then select **Activate**.

Business events can be activated either in all legal entities or in specific legal entities. If you leave the Legal entity field blank, the selected business events will be activated in all legal entities. If a business event is required only for specific legal entities, it must be configured separately for each legal entity.

Endpoints must be assigned to the business events that are activated. See **Manage business event endpoints** for additional information on setting up and managing endpoints.

When business events occur as business processes are run, the system will do outbound processing only for business events that have been activated.

After business events are activated, they appear on the **Active events** tab.

From the **Active events** tab, you can inactivate business events. The system won’t do outbound processing for inactivated events.
After business events are inactivated, they appear on the **Inactive events** tab.

Business events can be inactivated when processing of business events must be paused for a period because of specific system maintenance activities in the integration landscape.

When business requirements change, some business events might no longer be required. In this case, you can inactivate them instead of deleting them from the list of active events. This approach is useful if the history of errors for the business events must be preserved. Inactivated business events can be deleted later, when there is no longer a business need to keep them inactivated.

**Errors**

While the system does outbound processing of business events, errors can occur. These errors might prevent the system from successfully delivering a business event to the endpoint. If an error occurs, the system retries several times to successfully process the business event. However, if all attempts are unsuccessful, the business event is saved in an error log.

Error logs can be accessed from the **Active events**, **Inactive events**, and **Errors** tabs. The **Errors** tab shows all errors across all business events, whereas the other two tabs show errors in the context of a specific business event.

You can do on-demand outbound processing on each error by using the **Resend** action. This action invokes the outbound processing logic. This logic includes retries. If the outbound processing is still unsuccessful, the error is logged in the error log. In this case, the **Last process time** field on the **Errors** tab indicates when the last attempt to process the event occurred.

If an error can’t be successfully processed, you can use the **Download payload** option to download the payload from the event for offline processing, as you require.

**NOTE**

If an endpoint is deleted and a new endpoint is associated with business events, all errors that are associated with the business events can still be resent. In this case, the system will do outbound processing to send to the new endpoint that is associated with the corresponding business event. This functionality allows for graceful recovery from misconfiguration or other error states.

**Business event consumption models**

The integration requirements and integration solution design for implementations vary. The integration requirements play a role in identifying the consumption model for business events. In summary, you must consider the following points when you design integrations that use business events:
Business events can be consumed using Power Automate, Service Bus, Event Grid, or other endpoint types.

Customers must bring their own subscriptions to use Power Automate, Service Bus, Event Grid, or other endpoint types.

A business event can be activated in all legal entities or in specific legal entities.

A business event can be sent to a unique endpoint or multiple endpoints.

Power Automate can directly subscribe to business events.

### Idempotency

Business events enable idempotent behavior on the consuming side by having a control number in the payload. The control number is an upwardly increasing number, which can be tracked by the consuming application to detect duplication and/or out of order delivery. The control number cannot be misread as the sequence number because the control number cannot be sequential. There can be gaps in the numbering space.

### Filtering in Azure Event Grid and Azure Service Bus

Azure Service Bus and Azure Event Grid supports subscribing to topics by specifying criteria on the incoming message. For more information, see [Topic filters and actions](#) and [Understand event filtering for Event Grid subscriptions](#).

A business event that is sent to an Azure Service Bus or Azure Event Grid has the following fields made available for this purpose. Subscribers can use this information to subscribe to more specific topics as required.

- **Category** – This is the business event category as displayed in the business event catalog. This is useful as a filter criterion when a common topic is used for receiving business events from multiple categories and subscribers want to only receive business events for the category that they are interested in.

- **Business event ID** – This is the class name of the business event implementation as displayed in the business event catalog. This uniquely identifies the business event (not the instance of the business event) and thus helps in validation of received business events on the consumer side to ensure the expected business event is what is being received and processed.

- **Legal entity** – This is the legal entity in which the business event happened. This is a useful information to base the consuming logic on if the processing and distribution of business events on the consumption side must be driven by a legal entity.

<table>
<thead>
<tr>
<th>REQUIREMENT</th>
<th>PRIVILEGE</th>
<th>DUTY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only certain users must have access to view the business events catalog.</td>
<td><strong>BusinessEventsCatalogView</strong></td>
<td>None</td>
</tr>
<tr>
<td>Only certain users must have access to activate business events.</td>
<td><strong>BusinessEventsCatalogMaintain</strong></td>
<td>None</td>
</tr>
<tr>
<td>REQUIREMENT</td>
<td>PRIVILEGE</td>
<td>DUTY</td>
</tr>
<tr>
<td>---------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------</td>
<td>-------------------------------------------</td>
</tr>
<tr>
<td>Only certain users must have access to create and manage endpoints.</td>
<td>Business events security privilege</td>
<td>Business events security duty</td>
</tr>
<tr>
<td>Users must only be able to subscribe to business events which they have been granted access to from external applications like Power Automate.</td>
<td>Subscribe to business events from service</td>
<td>None</td>
</tr>
<tr>
<td>Only certain users must be able to view the business events security setup.</td>
<td>BusinessEventsCatalogSecuritySetUpView</td>
<td>None</td>
</tr>
<tr>
<td>Only certain users must be able to manage business events security.</td>
<td>Maintain business events catalog security</td>
<td>None</td>
</tr>
</tbody>
</table>

These privileges can be added to the required duties to grant corresponding roles appropriate access levels.

**Enabling role-based security for business events**

Role-based security for business events must be enabled via Feature management.

1. Go to System administration > Feature management.
2. Select the Business events catalog security feature.
3. Enable the feature.
4. Go to the business events catalog via System administration > Set up > Business events > Business events catalog.
5. The Security tab in the catalog is where a business event must be mapped to one or more roles. You must complete the configuration as required.
6. Enable security by selecting the Enable menu button on the Security menu on the top navigation pane. An informational message will confirm if security is enabled or disabled.
7. Modify the necessary security role to add the appropriate privilege or the duty based on security noted in the informational message.

**Subscribe to business events from service**

Users having access to the privilege Subscribe to business events from service via their roles will be able to only see and subscribe to business events that have been assigned to their roles, which is described below. The organizational assignments that are done, if any, as part of role-based security is honored in the context of business events by letting users to only subscribe to business events in the organizations to which they have access to via their roles. This behavior is effective using any service calls like from Power Automate or Logic Apps.

**Backward compatibility**

To ensure backward compatibility, the following behavior must be understood.

- Role-based security for business events will be disabled by default.
- Even if the feature is enabled in Feature management, role-based security will not take effect.
- Role-based security must be explicitly enabled in the business events catalog via the Security menu.
- After role-based security is enabled completely, security will be enforced henceforth. This will mean that any user with administration role will not notice any change in behavior. However, any non-admin users...
will either only see business events to which their roles were assigned to in the business events catalog security configuration or they will not see any business events because their roles were not assigned to any business events.

NOTE

To ensure uninterrupted functionality, it is important to understand the backward-compatibility behavior described above before you enable security on business events.
Endpoints let you manage the destinations that business events are sent to. Business events in Finance and Operations apps support the following endpoint types.

<table>
<thead>
<tr>
<th>ENDPOINT TYPE</th>
<th>TUTORIAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Azure Service Bus Queue</td>
<td>Business events and Azure Service Bus</td>
</tr>
<tr>

<td>HTTPS</td>
<td>Not applicable</td>
</tr>
<tr>
<td>Microsoft Power Automate</td>
<td>Business events and Microsoft Power Automate</td>
</tr>
<tr>
<td>Dataverse</td>
<td>Subscribe to events in Dataverse</td>
</tr>
</tbody>
</table>

Endpoints can be created for these messaging and event brokers out of the box. Some scenarios might require multiple endpoints for organized distribution of business events to consumers. You can create multiple endpoints to support these scenarios.

The Microsoft Azure–based endpoints must be in the customer's Azure subscription. For example, if Event Grid is used as an endpoint, the endpoint must be in the customer's Azure subscription.

A Finance and Operations app doesn't provision the endpoints. The endpoints must be created separately and provided to the app. The app then sends events to the endpoints that are provided. Customers might incur additional costs if they use these endpoints in their Azure subscription.

### Subscribing to Finance and Operations apps events from Dataverse

**IMPORTANT**

Before you subscribe to Finance and Operations apps business events and data events in Microsoft Dataverse, you must enable the Microsoft Power Platform integration. For information about how to enable the Microsoft Power Platform integration for a Finance and Operations apps environment, see [Enable the Microsoft Power Platform integration](#).

After the Microsoft Power Platform integration is enabled, you can subscribe to Finance and Operations apps business events and data events from Dataverse. Subscription enables the following capabilities:

- Consistent behavior across events from multiple applications in Dataverse
- Application Lifecycle Management (ALM) for the Dataverse solution to consistently consume events from Finance and Operations apps
- Registration of plug-ins and software development kit (SDK) steps on Finance and Operations apps events in
When the Microsoft Power Platform integration is enabled for a Finance and Operations apps environment, endpoints that are created for business events are synced with the linked Microsoft Power Platform environment for endpoint types that are supported in Dataverse. The endpoints can then be used in Microsoft Power Platform. When the endpoints are synced, business events that are sent from Finance and Operations apps are proxied through Dataverse to the endpoint.

The following table shows the mapping between the Finance and Operations apps and Dataverse implementations of the endpoints.

<table>
<thead>
<tr>
<th>FINANCE AND OPERATIONS APPS ENDPOINT TYPE</th>
<th>DATaverse SERVICE ENDPOINT TYPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Azure Service Bus Queue</td>
<td>Azure Service Bus of type Queue</td>
</tr>
<tr>
<td>Azure Service Bus Topic</td>
<td>Azure Service Bus of type Topic</td>
</tr>
<tr>
<td>Azure Event Grid</td>
<td>Azure Event Grid</td>
</tr>
<tr>
<td>Azure Event Hub</td>
<td>Azure Event Hub</td>
</tr>
<tr>
<td>HTTPS</td>
<td>Webhook</td>
</tr>
<tr>
<td>Azure Blob Storage</td>
<td>Not supported in Dataverse</td>
</tr>
<tr>
<td>Microsoft Power Automate</td>
<td>Asynchronous callback registration</td>
</tr>
<tr>
<td>Dataverse</td>
<td>Plug-in or SDK step registration</td>
</tr>
</tbody>
</table>

If an endpoint type isn't supported in Dataverse, or if the Microsoft Power Platform integration isn't enabled, the endpoint will continue to send the event from Finance and Operations apps instead of sending it through Dataverse.

**Viewing or creating mapped endpoints in Dataverse**

When a new endpoint is added in Finance and Operations apps, it's synced to Dataverse. It's then available for use in Dataverse in the `ServiceEndpoint` table. You can also create the endpoint directly in Dataverse in the `ServiceEndpoint` table. If the service endpoint is created by subscribing to a Finance and Operations apps event, it will automatically be made available to Finance and Operations apps and can be viewed on the `Endpoints` tab of the `Business events` page. This behavior is applicable to the following mapped endpoint types:

- Azure Service Bus Queue
- Azure Service Bus Topic
- Azure Event Grid
- Azure Event Hub

For more information about the `ServiceEndpoint` table, see [ServiceEndpoint table/entity reference](#).

**Microsoft Power Automate endpoints**

The Microsoft Power Automate endpoint type isn't made available for setup directly in Finance and Operations apps. This endpoint type is used for subscriptions that are created and sent directly from a flow in Power Automate.
The endpoint is created on the **Endpoints** tab of the **Business events** page in Finance and Operations apps when you subscribe to a Finance and Operations apps business event or data event in Power Automate. For more information about how to subscribe to business events and data events in Power Automate, see **Business events in Microsoft Power Automate**.

**Microsoft Dataverse endpoints**

The **Dataverse** endpoint type also isn’t available for manual setup in Finance and Operations apps. The endpoint is created when a plug-in or an SDK step is registered on a Finance and Operations apps business event or data event in Dataverse. When the step is registered, it becomes visible as an endpoint in the list on the **Endpoints** tab of the **Business events** page in Finance and Operations apps.

The business event registration itself will also be listed on either the **Business event catalog** tab or the **Data event catalog** tab of the **Business events** page in Finance and Operations apps, depending on registration. In this way, Finance and Operations apps users can learn which business event or data event has a plug-in or SDK step registered in Dataverse. They can also learn the reason why the event is active in Finance and Operations apps.

Finance and Operations apps events can be subscribed to directly in Dataverse by using the tools in the Dataverse toolset, such as the Power Platform Tools extension for Visual Studio. For more information about this extension, see **Install Power Platform Tools**. These subscriptions will appear on the **Business event catalog** tab of the **Business events** page in Finance and Operations apps.

Some attributes of service endpoints in Dataverse, such as the name and description, can be updated. These updates will also be reflected in Finance and Operations apps. However, updates that change the service endpoint type will be prevented if the service endpoint is used with Finance and Operations apps events. These updates include a change from a Service Bus topic to a Service Bus queue, which Dataverse usually allows. This behavior helps ensure design simplicity and consistency, because Finance and Operations apps don’t allow these updates to endpoints after they have been created.

After service endpoints are created, Dataverse doesn’t allow them to be deleted if they are being used. This limitation also applies to service endpoints that are used by Finance and Operations apps events. Any attempt to delete one of these endpoints will cause an error, and deletion will be prevented.

For more information about how to subscribe to Finance and Operations apps business events in Dataverse, see **Subscribe to events in Dataverse**.
This topic lists application business events.

### Procure to pay

<table>
<thead>
<tr>
<th>BUSINESS EVENT</th>
<th>DESCRIPTION</th>
<th>MODULE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vendor invoice matched</td>
<td>This event is triggered when invoice matching validation is completed for a vendor invoice as part of the Procure to pay process.</td>
<td>Accounts payable</td>
</tr>
<tr>
<td>Vendor invoice posted</td>
<td>This event business event is triggered when a user posts a vendor invoice as part of the Procure to Pay process.</td>
<td>Accounts payable</td>
</tr>
<tr>

<td>This event is triggered when a user posts an interest note as part of the Quote to Cash process.</td>
<td>Accounts receivable</td>
</tr>
<tr>
<td>Collection letter created</td>
<td>This event is triggered when a user creates a collection letter for a customer as part of the Quote to Cash process.</td>
<td>Credit and collections</td>
</tr>
</tbody>
</table>
Workflow business events are generated at various points in the processing of a workflow.

**Workflow construction**

To construct a workflow, a developer can define workflows components in metadata and code in the Visual Studio tools.

An administrator can create workflows in the web client and then design them in the workflow designer. For more information, see [Create workflows](#).

**Workflow components**

Workflow components are defined in metadata as:

- **Workflow types** - Also known as templates, workflow types define the elements allowed in a workflow. The administrator decides which elements are actually used when they create the workflow design.
  - In the Application Explorer, go to AOT > Business Process and Workflow > Workflow Types.
- **Workflow elements** - Workflow elements are the executable pieces that make up a workflow. For details, see [Workflow elements](#).
  - Tasks (aka manual tasks) - Go to AOT > Business Process and Workflow > Workflow Tasks.
  - Approvals - Go to AOT > Business Process and Workflow > Workflow Approvals.
  - Automated tasks - Go to AOT > Business Process and Workflow > Workflow Automated Tasks.

**Workflow runtime**

After a workflow is submitted by a user, it is added to a queue and run using the **Workflow message processing** batch job. As the workflow runs, it will progress through all the **connected workflow elements** until it reaches the end. When the workflow runtime encounters a **manual task element**, it will create a work item for the **user assigned to the task**. When the workflow runtime encounters an **approval element**, it will create a work item for each **user assigned to each approval step**.

**Workflow business event categories**

There are five different categories of workflow business events. The category will show up in Microsoft Power Automate to help with event selection.
- **Category: Workflow type**
  - These events will fire on workflow events like started and completed. All workflow instances will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID, for example "Workflow_BudgetPlanReview_000002"
  - **Name format** - Workflow label + "(" + Workflow instance ID ")", for example "Prepare department budget (000002)"

- **Category: Workflow element started**
  - These events will fire when a workflow element is started. All enabled workflow elements within a workflow instance will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID + "." + Workflow element name + ".Started", for example "Workflow_BudgetPlanReview_000002_BudgetActivateBudgetPlanChild_Started"
  - **Name format** - Workflow label + "(" + Workflow instance ID ") - " + Workflow element label, for example "Prepare department budget (000002) - Activate associated budget plan"

- **Category: Workflow element**
  - These events will fire on workflow element events other than started, such as completed. All enabled workflow elements within a workflow instance will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID + "." + Workflow element name, for example "Workflow_BudgetPlanReview_000002_BudgetActivateBudgetPlanChild"
  - **Name format** - Workflow label + "(" + Workflow instance ID ") - " + Workflow element label, for example "Prepare department budget (000002) - Activate associated budget plan"

- **Category: Workflow external task**
  - These events will fire when a workflow automated task element is started. All enabled workflow automated task elements within a workflow instance will be represented in this category.
  - **ID format** - "Workflow_" + Workflow name + Workflow instance ID + "." + Workflow element name + ".ExternalTask", for example "Workflow_BudgetPlanReview_000002_BudgetActivateBudgetPlanChild_ExternalTask"
  - **Name format** - Workflow label + "(" + Workflow instance ID ") - " + Workflow element label, for example "Prepare department budget (000002) - Activate associated budget plan"
• **Category: Workflow workitem**
  - These events will fire when a workflow work item is created for a user. All enabled workflow tasks and workflow approvals within a workflow instance will be represented in this category.
  - **ID format** - "Workflow._" + Workflow name + Workflow instance ID + "," + Workflow element name + "," + WorkItem", for example
    "Workflow_BudgetPlanReview_000002_BudgetActivateBudgetPlanChild_WorkItem"
  - **Name format** - Workflow label + " (" + Workflow instance ID ") - " + Workflow element label, for example "Prepare department budget (000002) - Activate associated budget plan"

### Completion of a work item in Power Automate

Workflow business events are a good target for triggering approval flows. The **workflow workitem** event can be used in conjunction with the validate and complete OData actions to facilitate completion of a work item in Power Automate.

An approval or task work item can be completed in Power Automate using the following steps:

1. **Trigger the Power Automate using the when a business event occurs trigger** targeting the appropriate **workflow workitem** event.
2. **Validate that the workflow workitem contains a valid set of information so it is ready for completion by calling the Validate method on the WorkflowWorkItems entity.**
3. **If the workitem is not ready for completion, then send a notification to the assigned user to let them know that there is a workitem that needs their attention.**
4. **If the workitem is ready for completion, then request a response from the assigned user by sending the available response options to the user.**
5. **After a response is provided, complete the workitem with that response by calling the Complete method on the WorkflowWorkItems entity.**

To enable external completion of work items, the work item action manager class needs to implement the IValidateWorkflowWorkItemAction interface. The standard WorkflowWorkItemActionManager class has implemented this interface. In Platform update 32, the TrvWorkflowWorkItemActionManager class was updated to implement the IValidateWorkflowWorkItemAction interface. Use the existing IValidateWorkflowWorkItemAction implementations as examples to notify updates about other WorkflowWorkItemActionManager classes.

For a step-by-step guide to setting up work item completion in Microsoft Power Automate, see **Consume workflow approval business events**.

### Templates for work item completion in Power Automate

The following templates for work item completion in Power Automate are available:

- **Complete Dynamics 365 for Finance and Operations workflow work items (PU26)**
- **Complete Dynamics 365 for Finance and Operations workflow work items (PU29)**

The Platform update 29 version gets completion options from the business event payload. These options were added in Platform update 29, and presented to the user via the approval action.

### Troubleshooting workflow business events

#### Troubleshooting workflow issues

Ensure that the workflow is running correctly and creating work items as expected. If the workflow doesn’t work inside the application so that state changes are occurring, then the events won’t occur. Adjust the workflow configuration as needed. If needed, review the workflow details in the **Workflow History form**.
Troubleshooting Power Automate issues

Ensure that the Power Automate subscription is available in the System administration > Setup > Business events > Business events catalog on the Active events tab. If the Power Automate subscription isn’t there, then check Power Automate and recreate it if needed.

Troubleshooting business events issues

Ensure that other business events are occurring by creating a Power Automate to trigger off another business event. For example, the Free Text Invoice Posted event can be triggered by simply creating a Free Text Invoice with a single line and posting it. For more information, see Troubleshoot business events.

Troubleshooting work item approval via Power Automate

If a flow is trying to handle approval for work items, but it isn’t firing, then verify these steps:

- Are the work items being created so the applicable user can see them waiting for approval in the web client?
- Is the event subscription from Flow visible in the Business Events form?
- Are the workflow configuration and the event subscription from Flow for the correct legal entity (company)?
The batch framework emits the following system business events.

<table>
<thead>
<tr>
<th>BUSINESS EVENT</th>
<th>DESCRIPTION</th>
<th>MODULE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Batch job started</td>
<td>This event is fired when a batch job is marked as running.</td>
<td>Batch</td>
</tr>
<tr>
<td>Batch job finished</td>
<td>This event is fired when a batch job is completed.</td>
<td>Batch</td>
</tr>
<tr>
<td>Batch job failed</td>
<td>This event is fired when a batch job fails.</td>
<td>Batch</td>
</tr>
<tr>
<td>Batch job cancelled</td>
<td>This event is fired when a batch job is canceled.</td>
<td>Batch</td>
</tr>
</tbody>
</table>

**Usage**

**Batch job started and batch job finished**

The **batch job started** and **batch job finished** events can be used to monitor and identify long-running batch jobs. They can also be used to notify stakeholders if a job takes longer than expected. By default, these events are turned off in the application.

**Batch job failed**

The **batch job failed** event can be used to monitor specific batch jobs for failure, and to notify stakeholders in real time. By default, this event is turned on in the application.

**Configure batch business events**

1. Go to System administration > Inquiries > Batch jobs.
2. On the Business events tab, update the settings to raise batch business events.

The events have the following payload.

<table>
<thead>
<tr>
<th>FIELD NAME</th>
<th>FIELD LABEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>JobId</td>
<td>Batch job ID</td>
</tr>
<tr>
<td>JobDescription</td>
<td>Batch job description</td>
</tr>
<tr>
<td>JobStatus</td>
<td>Batch job status</td>
</tr>
<tr>
<td>JobOwnerEmailId</td>
<td>Batch job owner email ID</td>
</tr>
<tr>
<td>JobExecutedByEmailId</td>
<td>Batch job executed by email ID</td>
</tr>
<tr>
<td>FIELD NAME</td>
<td>FIELD LABEL</td>
</tr>
<tr>
<td>------------------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>AdminEmailId</td>
<td>Admin user email ID</td>
</tr>
<tr>
<td>JobEndUtcDateTime</td>
<td>Job end UTC date time</td>
</tr>
<tr>
<td>BusinessEventId</td>
<td>Business event ID</td>
</tr>
<tr>
<td>ControlNumber</td>
<td>Business event control number</td>
</tr>
<tr>
<td>EventId</td>
<td>Business event instance ID</td>
</tr>
<tr>
<td>EventTime</td>
<td>Business event instance ID</td>
</tr>
<tr>
<td>MajorVersion</td>
<td>Major version</td>
</tr>
<tr>
<td>MinorVersion</td>
<td>Minor version</td>
</tr>
</tbody>
</table>

To get the current catalog and schema of business events, go to **System administration > Setup > Business events**.
There are two kinds of alerts that can be configured by users. These are change-based alerts and due date alerts. For more information about the alerts functionality, see Alerts.

The change-based alerts and due date alerts can be configured to send out a business event as a mechanism to notify or trigger external applications or systems. This allows alerts to participate in advanced user notification scenarios and also in business process integration across systems.

To generate a business event from an alert, in the Create alert rule dialog box, set Alert me with > Send externally to Yes.

In order for alerts to be processed, the batch processes for change-based and/or due-date alerts should be set for batch processing for due-date events. For more information, see Batch processing for due-date events.

The business event for the change-based alert and/or the due date alert must also be active for the alert to be sent out as a business event. To learn more about the activation process, see Activating business events.
Data events are events that are based on changes to data in Finance and Operations apps. Create, update, and delete (CUD) events can be enabled for each entity. For example, if the Create event is enabled for the Purchase order headers V2 entity, an event notification is emitted every time that a new purchase order is created in the database.

All standard and custom entities in Finance and Operations apps that are enabled for Open Data Protocol (OData) can emit data events. In the data event catalog, each event for an entity is listed as a data event that subscriptions can be established for. The concept of activating the data event and associating it with an endpoint resembles the concept of business events. When a data event occurs, the payload of the event contains the corresponding entity record.

Data events are available only in environments that the Microsoft Power Platform integration is enabled for. For more information, see Enable the Microsoft Power Platform integration.

Data event catalog

To access the data event catalog, select the Data event catalog tab on the Business events page (System administration > Setup > Business event). The data event catalog provides a complete list of the available data events in the Finance and Operations apps environment. For each data event, the list shows the category, event ID, and name. It also indicates whether the event is company-specific. You can filter the list by category and data event ID.

Activating data events

By default, data events are inactive. To activate a data event from the data event catalog, select it in the list, and then select Activate.
Data events can be activated either in all legal entities or in specific legal entities. In the **Configure new data event** dialog box, in the **Legal entity** field, select the legal entity that you want to activate the data events in. If you leave the **Legal entity** field blank, the selected data events will be activated in all legal entities. If a data event is required in multiple specific legal entities, it must be configured separately for each legal entity.

Only company-specific data events can be configured for specific legal entities. When you configure data events that aren’t company-specific, the **Legal entity** field isn’t editable, and the data events are enabled for all legal entities.

To activate a data event, select a configured endpoint. For information about how to configure endpoints business events and data events, see **Manage business event endpoints**.

When you activate a data event, it’s added to the list on the **Active data events** tab of the **Business events** page and becomes available for subscription through the selected endpoint.

### Deactivating data events

You can deactivate data events from the **Active data events** tab of the **Business events** page. To deactivate a data event, select it in the list, and then select **Deactivate**. The data event is removed from the list on the **Active data events** tab and added to the list on the **Inactive data events** tab.

Like business events, data events can be deactivated when business event processing is temporarily paused. A temporary pause might be required because of system maintenance, bulk data imports, or bulk data processing. Bulk data processing where data events are enabled on related data entities can send a high volume of data events that might not be required. This situation can affect system performance.

When data events are no longer required to meet business requirements, you can delete them from the list on the **Active data events** or **Inactive data events** tab. In this case, the data events are removed from the list, and all error history for them is deleted. If the history of errors for a data event must be preserved, you can deactivate the data event instead of deleting it. For more information about error logs for business events and data events, see **Errors**.

### Download the data event schema

The **Data event catalog** tab on the **Business events** page also shows the fields that are passed to a data event and that make up the event schema. The information that is shown includes the field name and label. You can download the JavaScript Object Notation (JSON) schema for an event by selecting **Download schema**.

**End of document**
This capability is helpful when external integration systems require the schema of the payload for a business event during development.
The Finance and Operations connector and Microsoft Dataverse connector are available for consuming business events in Microsoft Power Automate. The Finance and Operations connector has a **When a Business Event occurs** trigger. The Dataverse connector has a **When an action is performed** trigger. Either of these triggers can be used to subscribe to any of the business events that are available in Finance and Operations apps. Both triggers provide the same functionality, but the execution is slightly different.

The Dataverse connector lets you use the **When a row is added, modified or deleted** trigger to subscribe to data events in Finance and Operations apps. This trigger enables a Power Automate flow to be triggered by any create, update, or delete (CUD) event against a selected Finance and Operations apps entity.

**Prerequisite**

It's important that you understand business events. For more information, see the Business events documentation.

**Subscribing to business events**

**Using the Finance and Operations connector**

The Finance and Operations connector communicates directly with Finance and Operations apps to establish subscriptions, but it's triggered by Dataverse at runtime. The connector can connect to any instance of Finance and Operations apps on the Azure Active Directory (Azure AD) tenant.

After the **When a Business Event occurs** trigger is added to a flow, the following information must be provided:

- **Instance** – Specify the host name of the instance where business events occur. Environment instances should be available in the provided drop-down menu, but if an environment is not listed it can be entered as a custom value.
- **Category** – Select the category of business events. The list of unique business event categories in the business event catalog in Finance and Operations apps is shown.
- **Business event** – Select the business event that the flow should be triggered from. All the business events that are shown in the list are business events in the selected category in the Finance and Operations apps business event catalog.
- **Legal entity** – Specify the legal entity where the business event is being subscribed to. The flow will be triggered when the business event occurs in that legal entity. By default, this field is blank and the business event is subscribed to in **all** legal entities.

When the flow is saved, a subscription to the selected business event is added into the environment instance. As
Using the Dataverse connector

Business events for Finance and Operations apps are also exposed through the **When an action is performed** trigger of the Dataverse connector. This trigger exposes actions and table operations that are configured in Dataverse by using the **Catalog** and **CatalogAssignment** tables. This configuration provides a more generic business event framework in Dataverse that isn’t limited to Finance and Operations apps business events. Business events in the Finance and Operations apps business event catalog are synchronized with the Dataverse business events catalog. Therefore, you can subscribe to Finance and Operations apps business events to initiate business logic in a Power Automate flow. For more information about the catalog in the Dataverse business events framework, see **Catalog and CatalogAssignment tables**.

To use the Finance and Operations apps business events in the **When an action is performed** trigger of the Dataverse connector, the Microsoft Power Platform integration must be enabled for the Finance and Operations apps environment, so that the Finance and Operations apps environment is connected to the Dataverse environment. For more information about how to enable the Microsoft Power Platform integration for Finance and Operations apps environments, see **Enabling the Microsoft Power Platform integration**.

---

**NOTE**

The Microsoft Power Platform integration has a one-to-one connection between Finance and Operations apps and the Microsoft Power Platform environment. Because of this relationship, you can’t select among multiple Finance and Operations apps environments as the **When a Business Event occurs** trigger of the Finance and Operations connector does. The trigger automatically connects to the Finance and Operations apps environment that is selected for the Microsoft Power Platform integration.

---

After the **When an action is performed** trigger is added to a flow in Power Automate, the following information must be provided:

- **Catalog** – Select **Finance and Operations**. This exposes Finance and Operations business events as a Dataverse business events catalog.
- **Category** – Select the category of the desired business event. The list of unique business event categories in the business event catalog in Finance and Operations apps is shown.
- **Table name** – If the action is related to a specific table, select the related table. Typically, the value will be **(none)** for Finance and Operations apps business events.
- **Action name** – Select the action or business event that the flow should be triggered from. The drop-down list shows all synchronized business events in the selected category in the Finance and Operations apps business event catalog.

For more information about how to use the **When an action is performed** trigger in Power Automate, see **Trigger flows with actions**.
Subscribing to data events

Finance and Operations apps entities that are enabled as virtual entities in Dataverse are included in the **When a row is added, modified or deleted** trigger of the Dataverse connector. When you add the trigger to a flow in Power Automate, define the table name of the table that you want to trigger the flow for. The **Table name** list contains the list of all Finance and Operations apps entities that are exposed as virtual entities in Dataverse from the Finance and Operations apps environment that is connected to the Microsoft Power Platform environment through the Microsoft Power Platform integration. For information about how to enable virtual entities, see [Enable Dataverse virtual entities](#).

For more information about how to use the **When a row is added, modified or deleted** trigger in the Dataverse connector, including information about advanced options, see [Trigger flows when a row is added, modified, or deleted](#).

Unsubscribing from business events

If the trigger is deleted or the flow is turned off, the business event endpoint is automatically deleted.

Adjusting flow parameter limits

Multiple flows can subscribe to the same business event in different legal entities or in the same legal entity. The default endpoint limit per event is ten. You can adjust the **Endpoints allowed per event** setting on the **Business event parameters** page as you require.

Other ways to consume business events in Power Automate

The previous section explains how you can subscribe to business events directly from Power Automate by using the trigger in the connector. However, you can also consume business events in Microsoft Power Automate from Microsoft Azure Event Grid, by using the [Event Grid connector for Microsoft Power Automate](#).

Event Grid might be a viable approach for consuming business events in Power Automate if it’s already being used for other integrations in an implementation. If a business event in the same legal entity must trigger multiple flows, you should consider consuming the business event from Event Grid.
This approach is applicable to any messaging or event platform that is used as an endpoint for business events, provided that a connector is available for it in Power Automate.

For information about how to use business events in Microsoft Flow, see Consume business events in Microsoft Flow.
This topic walks you through the development process and best practices for implementing business events.

What is a business event, and what isn’t a business event?

This question comes up every time that we start to think about use cases where business events can help. Is the creation of a vendor a business event? Is confirmation of a purchase order a business event? Is it a business event if you capture the event at the table level? Or should business events be captured only at the business logic level in a business process? These questions aren’t just valid, but they are also a key topic of discussion when a solution is planned and architected for integration. The following guidelines can help with this thought process and decision making.

Intent

The intent behind capturing a business event must be clearly understood. In other words, what is the reason for capturing the business event, and how it will be used by the recipient?

If your intent is to capture a business event so that you can take a business action outside Dynamics 365 Finance and Operations apps in response to a business event that occurs in Finance and Operations, you have a good use case for business events. The business action that is taken in response to the business event can be to notify users about the business event and/or to call into another business application to take a business action, such as creation of a sales order. It's important that you look at the business action generically and not base the need for a business event on the type of business action that will be taken.

If your intent is to transfer data to a recipient and, in effect, realize a data export scenario, you don't have a good use case for business events. In fact, the use of business events for data transfer scenarios is a misuse of the business events framework. Such scenarios must continue to use data export mechanisms that are already available in data management.

Fidelity

When the intent is clear, and a legitimate need for a business event is established, the next step is to evaluate the approach that must be used to capture the business event. This section summarizes the approach that must be evaluated.

Regardless of the approach that is used, the fidelity of business events is significant, because it helps guarantee that the following aspects are taken care of. Therefore, it must influence the design choice for implementing the business event. However, the design choice that you make to implement a business event must not influence the concept of business events. In other words, the chosen design must not be used as a decision-making tool, to determine whether an event is a business event. The intent must be used to make those decisions.

- **Durable business events** – No false business events should be sent to the recipient. If a purchase order confirmation business event is sent out, the recipient expects and must trust that the purchase order was really confirmed. The design choice must help guarantee this transactional nature. Therefore, you must not make a design choice that violates the recipient's expectations.

- **Targeted** – Business events must be designed to optimize the consumption story for the recipient. In other words, you should make it as easy as possible for the recipient to consume business events. Therefore, business events must be as specific as possible and must be targeted to specific use cases. They must not be generic, so that the consumer has to determine what the business event is for by trying to understand the
payload. The design choice must allow for preservation of targeted business events.

- **Noiseless** – The design should include very little effort to filter out noise. To make business events very specific, avoid writing filtering logic to filter out conditions that don’t match the expected business event. The chosen approach must help guarantee that the business event is implemented in code at a sufficiently specific point so that no filtering of noise is required. Any attempt to filter noise by adding logic can affect performance and might also become complicated in specific use cases.

The following table compares capture at the business and table levels.

<table>
<thead>
<tr>
<th>CAPTURE AT THE BUSINESS LOGIC LEVEL</th>
<th>CAPTURE AT THE TABLE LEVEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Capture at this level helps guarantee durability because it occurs in the transaction.</td>
<td>Capture at this level helps guarantee durability because it occurs in the transaction.</td>
</tr>
<tr>
<td>Capture at this level allows for targeted business events.</td>
<td>Because events are captured at a lower level, it's difficult to provide targeted business events.</td>
</tr>
<tr>
<td>It's easy to remain noiseless.</td>
<td>It's difficult to remain noiseless unless additional effort is made to implement sound logic that filters out noise.</td>
</tr>
<tr>
<td>Capture at this level provides additional context for the business process, and can significantly improve the durability and quality of the payload.</td>
<td>Because events are captured at a lower level, business process context is probably lost.</td>
</tr>
</tbody>
</table>

**NOTE**

In general, if you implement business events at the table level, you might face other challenges, in addition to the challenges that are described in the preceding table. For example, if the business logic is run via a stored procedure that updates data in the underlying table, the business event might not even be generated, because it was implemented in the table insert method in X++. You might encounter additional challenges in specific use cases. Therefore, we don't recommend that you implement business events at the table level.

### Implement a business event

The process for implementing a business event and sending it is fairly straightforward.

1. Build the contract.
2. Build the event.
3. Add code to send the event.

Two classes must be implemented:

- **Business event** – This class extends the `BusinessEventsBase` class. It supports constructing the business event, building the payload, and sending the business event.

- **Business event contract** – This class extends the `BusinessEventsContract` class. It defines the payload of the business event and allows for population of the contract at runtime.

**BusinessEventsBase extension**

**Naming convention**

The names of business events should follow the pattern `<noun or noun phrase> <past tense action>BusinessEvent`. The `<noun or noun phrase>` part of the name should comply with existing definitions for application area prefixes.

**Examples**
VendorInvoicePostedBusinessEvent
CollectionLetterSentBusinessEvent

Implementation
The process of implementing an extension of the BusinessEventsBase class is straightforward. It involves extending the BusinessEventsBase class, and implementing a static constructor method, a private new method, methods to maintain internal state, and the buildContract method.

1. Implement a static newFrom<my_buffer> method. The <my_buffer> part of the method name is typically the table buffer that is used to initialize the business event contract.

```java
static public SalesInvoicePostedBusinessEvent newFromCustInvoiceJour(CustInvoiceJour _custInvoiceJour)
{
    SalesInvoicePostedBusinessEvent businessEvent = new SalesInvoicePostedBusinessEvent();
    businessEvent.parmCustInvoiceJour(_custInvoiceJour);
    return businessEvent;
}
```

2. Extend the BusinessEventsBase class.

```java
[BusinessEvents(classStr(SalesInvoicePostedBusinessEventContract),
    'AccountsReceivable:SalesOrderInvoicePostedBusinessEventName',
    'AccountsReceivable:SalesOrderInvoicePostedBusinessEventDescription',
    ModuleAxapta::SalesOrder)]
public class SalesInvoicePostedBusinessEvent extends BusinessEventsBase
```

Note the BusinessEvents attribute. This attribute provides the business events framework with information about the business event's contract, name, and description. It also provides the module that the business event is part of. Labels must be defined for the name and description arguments. However, these labels should be referenced without the at symbol (@) to avoid storing localized data.

3. Implement a private new method. This method is called only from the static constructor method.

```java
private void new()
{
}
```

4. Implement private parm methods to maintain internal state.

```java
private CustInvoiceJour parmCustInvoiceJour(CustInvoiceJour _custInvoiceJour = custInvoiceJour)
{
    custInvoiceJour = _custInvoiceJour;
    return custInvoiceJour;
}
```

5. Implement the buildContract method. Note that you need an EventContract stub for this step.

```java
[Wrappable(true), Replaceable(true)]
public BusinessEventsContract buildContract()
{
    return SalesInvoicePostedBusinessEventContract::newFromCustInvoiceJour(custInvoiceJour);
}
```

For extensibility, the buildContract method must have the Wrappable(true) and Replaceable(true)
Here is the complete implementation of the “Sales order invoice posted” business event.

```csharp
/// <summary>
/// Sales order invoice posted business event.
/// </summary>
[BusinessEvents(classStr(SalesInvoicePostedBusinessEventContract),
'AccountsReceivable:SalesOrderInvoicePostedBusinessEventName',
'AccountsReceivable:SalesOrderInvoicePostedBusinessEventDescription',
ModuleAxapta::SalesOrder)]
public class SalesInvoicePostedBusinessEvent extends BusinessEventsBase
{
    private CustInvoiceJour custInvoiceJour;
    private CustInvoiceJour parmCustInvoiceJour(CustInvoiceJour _custInvoiceJour =
    custInvoiceJour)
    {
        custInvoiceJour = _custInvoiceJour;
        return custInvoiceJour;
    }
    /// <summary>
    /// Creates a SalesInvoicePostedBusinessEvent from a CustInvoiceJour record.
    /// <summary>
    /// param name = "_custInvoiceJour"> CustInvoiceJour record <param>
    /// <returns>A SalesInvoicePostedBusinessEvent </returns>
    static public SalesInvoicePostedBusinessEvent
    newFromCustInvoiceJour(CustInvoiceJour _custInvoiceJour)
    {
        SalesInvoicePostedBusinessEvent businessEvent = new
        SalesInvoicePostedBusinessEvent();
        businessEvent.parmCustInvoiceJour(_custInvoiceJour);
        return businessEvent;
    }
    private void new()
    {
    }
    [Wrappable(true), Replaceable(true)]
    public BusinessEventsContract buildContract()
    {
        return SalesInvoicePostedBusinessEventContract::newFromCustInvoiceJour(custInvoiceJour);
    }
}
```

**BusinessEventsContract extension**

A business event contract class extends the `BusinessEventsContract` class. It defines and populates the payload of the business event. Although there is some variation across business events, the basic structure of the business event contract is consistent.

The process of implementing a business event contract involves extending the `BusinessEventContract` class, defining internal state, implementing an initialization method, implementing a static constructor method, and implementing `parm` methods to access the contract state.

1. Extend the `BusinessEventContract` class.

   ```csharp
   [DataContract]
   public final class SalesInvoicePostedBusinessEventContract extends
   BusinessEventsContract
   {
   }
   ```

   The class must have the `DataContract` attribute.

2. Add private variables to hold the contract state.
3. Implement a private initialization method.

```java
private void initialize(CustInvoiceJour _custInvoiceJour)
{
    invoiceAccount = _custInvoiceJour.InvoiceAccount;
    invoiceId = _custInvoiceJour.InvoiceId;
    salesId = _custInvoiceJour.SalesId;
    invoiceDate = _custInvoiceJour.InvoiceDate;
    invoiceDueDate = _custInvoiceJour.DueDate;
    invoiceAmount = _custInvoiceJour.InvoiceAmountMST;
    invoiceTaxAmount = _custInvoiceJour.SumTaxMST;
    legalEntity = _custInvoiceJour.DataAreaId;
}
```

The `initialize` method is responsible for setting the private state of the business event contract class, based on data that is provided through the static constructor method.

4. Implement a static constructor method.

```java
public static SalesInvoicePostedBusinessEventContract
newFromCustInvoiceJour(CustInvoiceJour _custInvoiceJour)
{
    var contract = new SalesInvoicePostedBusinessEventContract();
    contract.initialize(_custInvoiceJour);
    return contract;
}
```

The static constructor method calls a private `initialize` method to initialize the private class state.

5. Implement `parm` methods to access the contract state.

```java
[DataMember('InvoiceAccount'), BusinessEventsDataMember("@AccountsReceivable:InvoiceAccount")]
public CustInvoiceAccount parmInvoiceAccount(CustInvoiceAccount _invoiceAccount = invoiceAccount)
{
    invoiceAccount = _invoiceAccount;
    return invoiceAccount;
}
```

The `parm` methods should have the `DataMember('<name>')` and `BusinessEventsDataMember('<description>')` attributes. The name that you provide on the `DataMember` attribute (for example, 'InvoiceAccount') will be visible to data contract consumers. The description that you provide in the `BusinessEventsDataMember` attribute will be visible in the Business Events catalog user interface (UI) and used to describe this contract's data members.
/// <summary>
/// The data contract for a SalesInvoicePostedBusinessEvent
/// </summary>
[DataContract]
public final class SalesInvoicePostedBusinessEventContract extends BusinessEventsContract
{
    private CustInvoiceAccount invoiceAccount;
    private CustInvoiceId invoiceId;
    private SalesIdBase salesId;
    private TransDate invoiceDate;
    private DueDate invoiceDueDate;
    private AmountMST invoiceAmount;
    private TaxAmount invoiceTaxAmount;
    private LegalEntityDataAreaId legalEntity;

    /// <summary>
    /// Creates a SalesInvoicePostedBusinessEventContract from a CustInvoiceJour record.
    /// </summary>
    /// <param name="_custInvoiceJour"> CustInvoiceJour record</param>
    /// <returns>A SalesInvoicePostedBusinessEventContract </returns>
    public static SalesInvoicePostedBusinessEventContract newFromCustInvoiceJour(CustInvoiceJour _custInvoiceJour)
    {
        var contract = new SalesInvoicePostedBusinessEventContract();
        contract.initialize(_custInvoiceJour);
        return contract;
    }

    private void initialize(CustInvoiceJour _custInvoiceJour)
    {
        invoiceAccount = _custInvoiceJour.InvoiceAccount;
        invoiceId = _custInvoiceJour.InvoiceId;
        salesId = _custInvoiceJour.SalesId;
        invoiceDate = _custInvoiceJour.InvoiceDate;
        invoiceDueDate = _custInvoiceJour.DueDate;
        invoiceAmount = _custInvoiceJour.InvoiceAmountMST;
        invoiceTaxAmount = _custInvoiceJour.SumTaxMST;
        legalEntity = _custInvoiceJour.DataAreaId;
    }

    private void new()
    {
    }

    [DataMember('InvoiceAccount'), BusinessEventsDataMember('@AccountsReceivable:InvoiceAccount')]
    public CustInvoiceAccount parmInvoiceAccount(CustInvoiceAccount _invoiceAccount = invoiceAccount)
    {
        invoiceAccount = _invoiceAccount;
        return invoiceAccount;
    }

    [DataMember('InvoiceId'), BusinessEventsDataMember('@AccountsReceivable:BusinessEventInvoiceId')]
    public CustInvoiceId parmInvoiceId(CustInvoiceId _invoiceId = invoiceId)
    {
        invoiceId = _invoiceId;
        return invoiceId;
    }

    [DataMember('SalesId'), BusinessEventsDataMember('@AccountsReceivable:SalesId')]
    public SalesIdBase parmSalesId(SalesIdBase _salesId = salesId)
    {
        salesId = _salesId;
        return salesId;
    }

    [DataMember('InvoiceDate'), BusinessEventsDataMember('@AccountsReceivable:InvoiceDate')]
    public TransDate parmInvoiceDate(TransDate _invoiceDate = invoiceDate)
    {
        invoiceDate = _invoiceDate;
        return invoiceDate;
    }

    [DataMember('InvoiceDueDate'), BusinessEventsDataMember('@AccountsReceivable:InvoiceDueDate')]
    public DueDate parmInvoiceDueDate(DueDate _invoiceDueDate = invoiceDueDate)
    {
        invoiceDueDate = _invoiceDueDate;
        return invoiceDueDate;
    }

    [DataMember('InvoiceAmount'), BusinessEventsDataMember('@AccountsReceivable:InvoiceAmount')]
    public AmountMST parmInvoiceAmount(AmountMST _invoiceAmount = invoiceAmount)
    {
        invoiceAmount = _invoiceAmount;
        return invoiceAmount;
    }

    [DataMember('InvoiceTaxAmount'), BusinessEventsDataMember('@AccountsReceivable:InvoiceTaxAmount')]
    public TaxAmount parmInvoiceTaxAmount(TaxAmount _invoiceTaxAmount = invoiceTaxAmount)
    {
        invoiceTaxAmount = _invoiceTaxAmount;
        return invoiceTaxAmount;
    }

    [DataMember('LegalEntityDataAreaId'), BusinessEventsDataMember('@AccountsReceivable:LegalEntityDataAreaId')]
    public LegalEntityDataAreaId parmLegalEntity(LegalEntityDataAreaId _legalEntity = legalEntity)
    {
        legalEntity = _legalEntity;
        return legalEntity;
    }
}

In some cases, population of the data contract's internal state requires that you implement additional retrieval methods. These retrieval methods should be implemented as private methods, and they should be called from the initialize method.

Here is the complete implementation of the “Sales order invoice posted” business event contract.
public CustInvoiceId parmInvoiceId(CustInvoiceId _invoiceId = invoiceId)
{
    invoiceId = _invoiceId;
    return invoiceId;
}

public SalesIdBase parmSaleOrderId(SalesIdBase _salesId = salesId)
{
    salesId = _salesId;
    return salesId;
}

public TransDate parmInvoiceDate(TransDate _invoiceDate = invoiceDate)
{
    invoiceDate = _invoiceDate;
    return invoiceDate;
}

public DueDate parmInvoiceDueDate(DueDate _invoiceDueDate = invoiceDueDate)
{
    invoiceDueDate = _invoiceDueDate;
    return invoiceDueDate;
}

public AmountMST parmInvoiceAmount(AmountMST _invoiceAmount = invoiceAmount)
{
    invoiceAmount = _invoiceAmount;
    return invoiceAmount;
}

public TaxAmount parmInvoiceTaxAmount(TaxAmount _invoiceTaxAmount = invoiceTaxAmount)
{
    invoiceTaxAmount = _invoiceTaxAmount;
    return invoiceTaxAmount;
}

public LegalEntityDataAreaId parmLegalEntity(LegalEntityDataAreaId _legalEntity = legalEntity)
{
    legalEntity = _legalEntity;
    return legalEntity;
}

Sending a business event

You must modify application code so that it sends the business event at the appropriate point. Often, you can use a common point in a framework. Documents that extend SourceDocument have a common point for creating and sending a business event. For more information, see the Source document framework support section later in this topic.

Other frameworks also provide common points for sending business events. For example, the CustVendVoucher class hierarchy in the Application Object Tree (AOT) has a post method that is used to send business events that are related to posting customer or vendor vouchers. Overrides of the base class implementation provide specialization of the logic for sending business events. For an example, see CustVoucher.createBusinessEvent or VendVoucher.createBusinessEvent in the AOT.

The sending of a business event is linked to the commit of the underlying transaction. If the underlying transaction is aborted, the business event won’t be sent. Therefore, applications can send the business event at the point where the payload information is available.
if (BusinessEventsConfigurationReader::isBusinessEventEnabled(classStr(CollectionStatusUpdatedBusinessEvent)))
{
    while select dispute
        where dispute.Status == CustVendDisputeStatus::PromiseToPay
            && dispute.FollowUpDate _currentDate
        exists join custTrans
            where custTrans.RecId == dispute.CustTrans
                && !custTrans.Closed
        exists join _tmpCustAging
            where _tmpCustAging.AccountNum == custTrans.AccountNum
    {
        CollectionStatusUpdatedBusinessEvent::newFromCustDispute(dispute).send();
    }
}

Source document framework support

The source document framework supports sending business events automatically as part of the transition from an in-process state to a completed state for the document. To take advantage of this capability, documents that extend the source document framework must implement an extension of the SourceDocumentStateInProcess.getBusinessEvent method to create and return the correct BusinessEventsBase extension type.

Extending a business event payload

You might want to publish additional information as part of the payload of a business event. To send this additional information, you must extend the business event's standard payload.

Example scenario

This example shows how to extend the CustFreeTextInvoicePostedBusinessEventContract class so that it includes a customer classification. This customer classification is an industry-based custom classification.

Step 1: Create an extended business event contract

Create a contract that consists of the standard business event contract plus any additional information that must be included in the payload.

[DataContract]
public class CustFreeTextInvoicePostedBusinessEventExtendedContract extends BusinessEventsContract
{
    // standard contract
    // contract extensions
    private str customerClassification;
}

Step 2: Create an initialize method

Create an initialize method that initializes the value of the private contract.
private void initialize(CustFreeTextInvoicePostedBusinessEventContract _custFreeTextInvoicePostedBusinessEventContract) {
}

Step 3: Create a static newFrom method
Create a static newFrom method that takes the standard contract as an argument and calls the initialize method.

    var contract = new CustFreeTextInvoicePostedBusinessEventExtendedContract();
    contract.initialize(_custFreeTextInvoicePostedBusinessEventContract);
    return contract;
}

Step 4: Map parm methods
Copy the parm methods from the standard data contract, and modify each method so that it gets and sets values in the class's standard contract instance.

[DataMember('InvoiceAccount')]
public CustInvoiceAccount parmInvoiceAccount(CustInvoiceAccount _invoiceAccount = custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount()) {
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount(_invoiceAccount);
}

[DataMember('InvoiceId')]
public CustInvoiceId parmInvoiceId(CustInvoiceId _invoiceId = custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId()) {
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId(_invoiceId);
}

Step 5: Add parm methods for additional payload data

[DataMember('CustomerClassification')]
public CustomerClassification parmCustomerClassification(CustomerClassification _customerClassification = customerClassification) {
    customerClassification = _customerClassification;
    return customerClassification;
}

Here is the complete implementation of the extended business contract.

[DataContract]
public class CustFreeTextInvoicePostedBusinessEventExtendedContract extends BusinessEventsContract {
    // standard contract
    // contract extensions
    private str customerClassification;
        var contract = new CustFreeTextInvoicePostedBusinessEventExtendedContract();
        contract.initialize(custFreeTextInvoicePostedBusinessEventContract);
        return contract;
    }
    public CustInvoiceAccount parmInvoiceAccount(CustInvoiceAccount _invoiceAccount) {
        return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount(_invoiceAccount);
    }
    public CustInvoiceId parmInvoiceId(CustInvoiceId _invoiceId) {
        return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId(_invoiceId);
    }
    public CustomerClassification parmCustomerClassification(CustomerClassification _customerClassification) {
        customerClassification = _customerClassification;
        return customerClassification;
    }
}
{
    var contract = new CustFreeTextInvoicePostedBusinessEventExtendedContract();
    contract.initialize(_custFreeTextInvoicePostedBusinessEventContract);
    return contract;
}
private void initialize(CustFreeTextInvoicePostedBusinessEventContract custFreeTextInvoicePostedBusinessEventContract)
{
}
private void new()
{
}

[DataMember('InvoiceAccount')]
public CustInvoiceAccount parmInvoiceAccount(CustInvoiceAccount _invoiceAccount = custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount())
{
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAccount(_invoiceAccount);
}

[DataMember('InvoiceId')]
public CustInvoiceId parmInvoiceId(CustInvoiceId _invoiceId = custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId())
{
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceId(_invoiceId);
}

[DataMember('InvoiceDate')]
public TransDate parmInvoiceDate(TransDate _invoiceDate = custFreeTextInvoicePostedBusinessEventContract.parmInvoiceDate())
{
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceDate(_invoiceDate);
}

[DataMember('InvoiceDueDate')]
public DueDate parmInvoiceDueDate(DueDate _invoiceDueDate = custFreeTextInvoicePostedBusinessEventContract.parmInvoiceDueDate())
{
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceDueDate(_invoiceDueDate);
}

[DataMember('InvoiceAmountInAccountingCurrency')]
public AmountMST parmInvoiceAmount(AmountMST _invoiceAmount = custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAmount())
{
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceAmount(_invoiceAmount);
}

[DataMember('InvoiceTaxAmount')]
{
    return custFreeTextInvoicePostedBusinessEventContract.parmInvoiceTaxAmount(_invoiceTaxAmount);
}

[DataMember('LegalEntity')]
public LegalEntityDataAreaId parmLegalEntity(LegalEntityDataAreaId _legalEntity = custFreeTextInvoicePostedBusinessEventContract.parmLegalEntity())
{
    return custFreeTextInvoicePostedBusinessEventContract.parmLegalEntity(_legalEntity);
}

// contract extensions
[DataMember('CustomerClassification')]
public CustomerClassification parmCustomerClassification(CustomerClassification _customerClassification = customerClassification)
Step 6: Wrap the buildContract method

Provide a build contract implementation that calls `next` to load the standard business event contract and populates any payload extensions. Here is the complete class.

```java
[ExtensionOf(classStr(CustFreeTextInvoicePostedBusinessEvent))]
public final class FreeTextInvoicePostedBusinessEventContract_Extension
{
    public BusinessEventsContract buildContract()
    {
        var businessEventContract =
            CustFreeTextInvoicePostedBusinessEventExtendedContract::newFromCustFreeTextInvoicePostedBusinessEventContra
t(next
                buildContract());
        businessEventContract.parmCustomerClassification(CustomerClassifier::deriveCustomerClassification(businessEv
entContract.parmInvoiceAccount()));
        return businessEventContract;
    }
}
```

Extending filters so that they have custom fields (if the middleware supports this extension)

Some middleware systems allow for filtering of the events. For example, Microsoft Azure Service Bus has a property bag that can be populated with key-value pairs. These key-value pairs can be used to filter events when reading from the Service Bus Queue or Topic. Additionally, Azure Event Grid has filterable message properties such as `Subject`, `Event Type`, and `ID`. To support these various properties for the different systems, the business events framework uses a concept that is named `payload context`. This concept can be extended so that it includes custom fields that the different eventing systems can use for filtering.

**Payload context**

The business events framework supports the payload context concept. Payload context provides a way to decorate messages that the framework sends with context about the payload. In some scenarios, additional context might be required when messages are sent to endpoints. Therefore, the framework has hookpoints where the context can be overwritten and the adapters can be customized.

**Step 1: Add a custom payload context**

A custom payload context must be extended from the `BusinessEventsCommitLogPayloadContext` class.

```java
class CustomCommitLogPayloadContext extends BusinessEventsCommitLogPayloadContext
{
    private utcdatetime eventTime;
    public utcdatetime parmEventTime(utcdatetime _eventTime = eventTime)
    {
        eventTime = _eventTime;
        return eventTime;
    }
}
```

**Step 2: Construct the custom payload context**

A Chain of Command (CoC) extension must be written for the `BusinessEventsSender.buildPayloadContext`
Step 3: Consume the custom payload context from an adapter

Adapters that consume payload context are written in such a way that they expose CoC methods that allow for the consumption of new payload contexts. The following example shows what this step looks like for the Service Bus adapter. This adapter has a generic property bag that Service Bus consumers can filter on.

The BusinessEventsServiceBusAdapter class has the CoC method that is named addProperties.

Adding a custom endpoint type

The business events framework supports the addition of new endpoint types to the out-of-box endpoint types. This section provides an example that shows how to add new custom endpoint types.

Step 1: Add a new endpoint type

Each endpoint type is represented by the BusinessEventsEndpointType enum. The first step in the process of adding a new endpoint is to extend this enum, as shown in the following illustration.
Step 2: Add a new endpoint table to the hierarchy

All endpoint data is stored in a hierarchy table. The root of this table is the BusinessEventsEndpoint table. A new endpoint table must extend this root table by setting the Support Inheritance property to Yes and the Extends property to "BusinessEventsEndpoint" (or any other endpoint in the BusinessEventsEndpoint hierarchy).

The new table then holds the definition of the custom fields that are required to initialize and communicate with the endpoint in code. To help avoid conflict, you should qualify field names to the specific endpoint where they belong. For example, two endpoints can have the concept of a URL field. To distinguish the fields, names should be specific to the custom endpoint. For example, name the field for the custom endpoint CustomURL.

Step 3: Add a new endpoint adapter class that implements the IBusinessEventsEndpoint interface

The new endpoint adapter class must implement the IBusinessEventsEndpoint interface. It must also be decorated with the BusinessEventsEndpointAttribute attribute.

```java
[BusinessEventsEndpoint(BusinessEventsEndpointType::CustomEndpoint)]
public class CustomEndpointAdapter implements IBusinessEventsEndpoint
{

```

The initialize method should be implemented to check the type of the BusinessEventsEndpoint buffer that is passed in, and then, if the buffer is of the correct type, initialize it, as shown in the following example.
if (!_endpoint is CustomBusinessEventsEndpoint)
{
    BusinessEventsEndpointManager::logUnknownEndpointRecord(tableStr(CustomBusinessEventsEndpoint),
        _endpoint.RecId);
}

CustomBusinessEventsEndpoint customBusinessEventsEndpoint = _endpoint as
CustomBusinessEventsEndpoint;
customField = customBusinessEventsEndpoint.CustomField;
if (!customField)
{
    throw warning(strFmt("@BusinessEvents:MissingAdapterConstructorParameter",
        classStr(CustomEndpointAdapter), varStr(customField)));
}

Step 4: Extend the EndpointConfiguration form

Add a new group control under
FormDesign/BusinessEventsEndpointConfigurationGroup/EndpointFieldsGroup/ to hold your custom field input.

The custom field input should be bound to the new table and field that you created in the previous step. Create a
class extension to extend the getConcreteType and showOtherFields methods of
BusinessEventsEndpointConfiguration form, as shown in the following example.
```java
final public class CustomBusinessEventsEndpointConfiguration_Extension {
    public TableName getConcreteTableType(BusinessEventsEndpointType _endpointType) {
        TableName tableName = next getConcreteTableType(_endpointType);
        if (_endpointType == BusinessEventsEndpointType::CustomEndpoint) {
            tableName = tableStr(CustomBusinessEventsEndpoint);
        }
        return tableName;
    }

    public void showOtherFields() {
        next showOtherFields();
        BusinessEventsEndpointType selection = any2Enum(EndpointTypeSelection.selection());
        if (selection == BusinessEventsEndpointType::CustomEndpoint) {
            this.control(this.controlId(formControlStr(BusinessEventsEndpointConfiguration, CustomFields))).visible(true);
        }
    }
}
```

Adding human-readable data fields to the payload

This feature is available in Platform update 30 and later.

The serialization of business events uses FormJsonSerializer to serialize objects in the data contract. FormJsonSerializer can format `UtcDateTime` values in the ISO 8601 date and time format. This format is human-readable when the payload of a business event is viewed. For example, a `UtcDateTime` value can now be formatted as "2007-12-05T14:30Z" instead of "/Date(1196865000000)". In the "/Date(N)" format, N is the number of milliseconds that have passed since January 1, 1970, UTC+0. The ISO format is more often understood by tools that parse JavaScript Object Notation (JSON).

To get the human-readable format, use the extended data type (EDT) that is named `DateTimeIso8601` as the type of the value in the data contract. Alternatively, use an EDT that is derived from the `DateTimeIso8601` EDT.

```java
[DataMember("TestIsoEdtUtcDateTime")]
public DateTime Iso8601 testIsoEdtUtcDateTime(DateTime Iso8601 _value = this._testIsoDateTime) {
    if (!prmIsDefault(_value)) {
        this._testIsoDateTime = _value;
    }
    return this._testIsoDateTime;
}
```
This topic provides tips for troubleshooting issues that involve business events.

<td>ISSUE</td>
<td>POSSIBLE RESOLUTION</td>
</tr>
<tr>
<td>-------</td>
<td>---------------------</td>
</tr>
<tr>
<td>Business events do not show up in the Business event catalog in Finance and Operations apps.</td>
<td>The Business event catalog is built during the full database sync. As a result, there are some use cases, as noted below, where a manual refresh of the catalog is needed in order to see the new business events. A manual refresh can be invoked from the catalog by going to Manage &gt; Rebuild business events catalog. When you are implementing business events in Visual Studio you may not see the newly-coded business event in the catalog. When new workflows are configured, such as the workflow elements or steps, events might not show up in the business events catalog. In other situations, when you don’t see certain business events, doing a manual refresh should resolve the issue.</td>
</tr>
<tr>
<td>Finance and Operations business events are not available in the Catalog Assignment tab of the virtual entity solution in the Power Platform maker portal.</td>
<td>Business events that are available in the Business event catalog in Finance and Operations apps should sync automatically to the virtual entity solution in the Power Platform portal. If the business events are not available in the Power Platform portal automatically, a sync can be triggered manually by using the Rebuild business event catalog action on the Manage menu of the Business event catalog page.</td>
</tr>
<tr>
<td>- 0 is an invalid bundle size - Business events are not getting triggered - Microsoft Flow is not getting triggered by business events - Unable to configure business event because it has reached the limit of 0 configured endpoints</td>
<td>One of the reasons why this issue can occur is if certain parameters are not set as expected in the BusinessEventsParameters table. This is due to an update in which some of the business events parameters not being set correctly. In a non-production environment, you must update the parameters in System administration &gt; Setup to set retry count = 3; End points allowed per event = 10 and wait time = 1000. After this update, restart the batch service and run IISReset to pick up the latest values. If business events still do not trigger, then the dedicated capacity is not working to process business events. A manual batch job must be scheduled to process business events, which can be enabled from the Business events parameters page in System administration &gt; Set up.</td>
</tr>
<tr>
<td>Platform update 30 compiler warning when creating custom payload context fields by augmenting via Chain of Command (CoC) the addProperties method in the adapter class. Class 'BusinessEventsServiceBusAdapter' is internal in model 'ApplicationFoundation' and cannot be extended.</td>
<td>This is a change in the compiler that prevents an internal API from being extended. This is being tracked as a bug to provide alternate ways to add custom properties. For more information, see this Yammer discussion.</td>
</tr>
<tr>

</tbody>
</table>
The following are potential use cases for business events. These use cases aren’t an exhaustive list of the potential use cases. Some of these use cases may not have been implemented yet either by Microsoft or other organizations. These use cases are meant to provide ideas and help with understanding business events.

<table>
<thead>
<tr>
<th>BUSINESS PROCESS</th>
<th>USE CASE</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Procurement</td>
<td>The procurement process frequently relies on manual intervention, so automating this process should increase procurement manager productivity.</td>
<td>You can make the procurement process more efficient by alerting procurement managers when quotation requests are sent, allowing for prompt follow-up and faster engagement. The goal is to have procurement managers follow up within three days and possibly create a Microsoft Power Automate that automates this follow up.</td>
</tr>
<tr>
<td>Procurement</td>
<td>Many organizations use manual processes to communicate internally and externally about production orders. Some organizations have complex approval processes for production orders, and need quick and easy ways to review and approve orders.</td>
<td>By creating business events that are triggered when production orders are updated, you can help improve communications between the back office and the production floor. When integration is required with third-party systems for production, the business events can also be used to help simplify the integration process.</td>
</tr>
<tr>
<td>Reporting</td>
<td>Managers are not informed about newly created financial reports. As a result, managers might analyze and make decisions based on outdated data.</td>
<td>You can make the reporting process more efficient by alerting managers when financial reports are sent, allowing for prompt follow-up and faster engagement. The goal is to have managers follow up within three days and possibly create a Power Automate that automates this follow-up.</td>
</tr>
<tr>
<td>Customer master</td>
<td>When a new customer is created, a credit limit check is needed. If something could automatically trigger an API that subscribes to a credit limit, and then check the website and import-specific credit limit check fields, such as limit amount and rating. At the same time, an approval Power Automate needs to start so that the customer account can be used after approval from management.</td>
<td>This check is required by many companies, especially in the retail area. This use case would be beneficial because partners develop customizations for this purpose.</td>
</tr>
<tr>
<td>BUSINESS PROCESS</td>
<td>USE CASE</td>
<td>VALUE</td>
</tr>
<tr>
<td>------------------</td>
<td>----------</td>
<td>-------</td>
</tr>
<tr>
<td>Month end close</td>
<td>The month-end closing schedule is a simple list that does not allow automatic actions. If functionality could be created to inform a group of people about tasks that have been completed and verified as complete, then a different group of people could start working.</td>
<td>Use real-life scenarios to enhance the currently static and difficult to use month-end closing workspace. One such use case is explained in detail in Business events in Financial Period Close.</td>
</tr>
<tr>
<td>Month end close</td>
<td>If functionality could be created to trigger a Power Automate when the status of a period is changed – either opened or closed.</td>
<td>Users are not automatically informed when new periods are opened after the month-end close is completed and they are allowed to start recording transactions in the new period.</td>
</tr>
<tr>
<td>Vendor master</td>
<td>If you are using the supplier (vendor) collaboration workspace, there is no automated way to inform the supplier that a new record has been created or existing records have been updated. This is an issue with requests for quotation and purchase orders. This means that the supplier would need to review the supplier collaboration workspace in case there are issues.</td>
<td>Using business events, the supplier portal functionality will provide improved productivity and efficiency by removing the need for additional correspondence between the supplier and the application. This is a true collaboration and will lead to supply chain efficiency. Without this functionality, the organization must follow up on all new requests or updates with phone calls or emails to the suppliers. This improves the supplier collaboration workspace.</td>
</tr>
<tr>
<td>Vendor master</td>
<td>Many organizations use manual, offline, and paper-based processes to manage vendors. Additionally, in many organizations, there are “gate keepers” that manage the master data. When updates occur to vendor master data, communication throughout the organization is limited or complex.</td>
<td>By integrating with Power Automate and creating business events for actions and events that regularly occur with vendor master data, you can help improve the overall vendor onboarding process. You can also help improve internal communications within your organization and automate business processes with your trade partners.</td>
</tr>
<tr>
<td>BUSINESS PROCESS</td>
<td>USE CASE</td>
<td>VALUE</td>
</tr>
<tr>
<td>------------------</td>
<td>----------</td>
<td>-------</td>
</tr>
<tr>
<td>Sales quotation</td>
<td>A quotation is placed for a personalized product. After the quotation is won this needs to become a real product. Requests are sent to a Data team (using PowerApps or Office) to create the item. After the item has been manually created, the item on the line is updated and the quote triggers the creation of a sales order. Currently, when the item is created, the approach is to wait for the data integrator to copy it to Dataverse. Monitors are set to find new entries on Dataverse and compare the unique references to any open numbers. Ideally, an item created business event exists, which is extended so that it has the unique identifier. This event is then subscribed to (in Power Automate or PowerApps) and immediately updates the quote line.</td>
<td>Using business events, the business would be able to update the won quote with the new product when the new product is created. This removes possible delays, manual updates, and errors.</td>
</tr>
<tr>
<td>Sales orders</td>
<td>Shipment for sales orders starts in a different system to enable logistics balancing of third-party haulers, production of customs, and delivery documentation. This pushes the data to a major transport company. Upon picking or shipment of a sales order, the line details are the event that triggers the external system to analyze and determine the details of the utilized shipment. This pushing event depends on the ability for a business action to update the application. This could be that the order is picked and then the shipment information pushed to the application, or it is marked as shipped as it is pushed externally.</td>
<td>This allows businesses with third-party transport companies to send shipping information to their vendors. This approach puts the responsibility of dispatch utilization on the external vendors and simplifies the setup.</td>
</tr>
<tr>
<td>Sales orders</td>
<td>Picking for sales orders can be performed in different systems, whether it's a separate internal warehousing system or a third-party location that is not part of the application. Upon confirmation or picking of a sales order, the line details are the event that triggers the external system to analyze and determine the picking priority and utilization.</td>
<td>This allows businesses with third-party warehouses to send the picking information to the system. This can also be used if the warehouse has automated picking machines that determine what is required. This approach puts the responsibility of prioritizing picking and utilization on the external system and simplifies the setup in the application.</td>
</tr>
<tr>
<td>BUSINESS PROCESS</td>
<td>USE CASE</td>
<td>VALUE</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Sales orders</td>
<td>Organizations are looking for ways to improve customer service, and to streamline and automate sales processes. These processes might involve several people, require many manual steps, or involve several third-party solutions. The email notification profile feature in Finance and Operations has limited email formatting capabilities.</td>
<td>By integrating with Power Automate and creating business events for actions that are taken on sales orders, you can help improve the overall sales process, help increase customer satisfaction, and automate collaboration between sales and operations.</td>
</tr>
<tr>
<td>Batch processing</td>
<td>Scheduling batch jobs to process polling logic can constrain resources. To realize near real-time processing, it is compelling to schedule the batch to run as fast as it can in Finance and Operations, which typically ends up being every few minutes. These batch jobs are typically data import/export jobs that look for data to be processed. However, if data is not available the batch job processes empty cycles, which can consume system resources.</td>
<td>Using business events, the polling use case can be redesigned to be asynchronous if it is triggered by the business event. Data will be processed only when it is available. The business logic that makes the data available triggers the business event, which can then be used to start the data processing job/logic. This can save thousands of batch executions from running empty cycles and wasting system resources.</td>
</tr>
<tr>
<td>Production orders</td>
<td>The production scheduling process often relies on external systems or optimization engines to finalize the schedule. Automation of the process and an ability to integrate with external systems when a production order is scheduled can help increase productivity and decrease integration costs.</td>
<td>You can improve the integration and automation capabilities by creating a business event when a production order is scheduled. The information can be communicated to downstream systems, such as Microsoft Dynamics 365 Field Service for Internet of Things (IoT) data exchange, third-party manufacturing execution systems (MESs), or a scheduling optimization engine.</td>
</tr>
<tr>
<td>Production orders</td>
<td>Many organizations use third-party MESs to control and manage their machinery on the production floor. Integration with these systems is often complex. Additionally, communication between the production floor and the back office can be difficult.</td>
<td>By creating business events that are triggered when production orders are updated, you can help improve communications between the back office and the production floor. When integration is required with third-party systems for production, the business events can also be used to help simplify the integration process.</td>
</tr>
<tr>
<td>BUSINESS PROCESS</td>
<td>USE CASE</td>
<td>VALUE</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Case management</td>
<td>Case management is a platform feature that lets you track and manage various requests and issues that are internally or externally reported or requested. Typically, each type of case has a different process, and various contributors to the case might be involved throughout the case’s lifecycle. The processes can be manual, and communication can often be delayed. Sometimes, contributors to the cases or stakeholders in them might not be users of the system.</td>
<td>By using Power Automate when cases are updated, you can streamline and automate the business processes that are related to various case types. You can also automate communication and implement approval processes when necessary, depending on your organizational requirements.</td>
</tr>
<tr>
<td>Transportation management</td>
<td>Many organizations have separate and disconnected systems for managing transportation. Additionally, the staff that is responsible for arranging transportation is typically not the same staff that creates and confirms orders, or the same staff that carries out the work to ship or receive orders. This situation can lead to a breakdown or lack of communication, and can require manual processes to notify various departments when an order is ready for the next step in the process. In many cases, third-party shipping software is used, and data is entered into many systems or tracked in paper logs.</td>
<td>By using business events together with Power Automate, you can streamline the overall transportation management process and help improve communications between departments.</td>
</tr>
</tbody>
</table>
This topic explains how to configure and consume a business event from a Microsoft Power Automate endpoint by using the **When a Business Event occurs** trigger of the Finance and Operations connector.

This topic shows how to perform the following tasks:

- Create a new flow in Power Automate.
- Trigger a business event.

The steps in this topic show how use the Finance and Operations connector. However, they can also be applied to the process of creating flows in Power Automate for Finance and Operations apps business events and data events in the Microsoft Dataverse connector. For more information about Finance and Operations apps business events and data events that have the **When an action is performed** and **When a row is added, modified or deleted** triggers in the Dataverse connector, see [Business events in Microsoft Power Automate](#).

## Create a new flow in Power Automate

1. Sign in to Power Automate portal.
2. Select an existing environment where you have the permissions needed to create a Power Automate resource. The default environment is open to all companies.
3. Select **New > Create from blank**.
4. Search for [Dynamics 365 for Finance and Operations](#) and select the connector.
5. You will notice a trigger named **When a Business Event occurs**. Select this trigger.
6. Select your environment instance, category, event name, and legal entity.

### TIP

Take advantage of the auto-complete that Power Automate provides by entering only part of the environment instance URL or part of the event name.

7. Select the **New Step** button to add a new action.
8. Search for the **Parse JSON** data operation. This step is needed to parse the message with the schema of the data contract.
9. Select the content field of **Parse Json** action, then the **Body** output from the previous step should appear as an option. Select **Body**.

10. Enter the schema of the contract. Because the app provides only a sample payload you can use the Power Automate capability to generate a schema from a payload. Select an event in the catalog (for example, Customer Payment) and select the **Download schema** link. This will download a text file. Open the text file and copy the content.

11. Go Back to Power Automate and select the **Use sample payload to generate schema** link. Paste your text file content and select **Done**.
12. Depending on the quality of your sample payload, your generator will not be able to distinguish between an integer and a real number. This is true if the real number is provided as a whole number in the sample payload. Review your generated schema and check if you need to change an “integer” into “number”. (In JSON, a “number” data type means real number).

13. Choose another final action to consume the business event content. For instance, you can send an email (or post a text message to Teams) to notify the customer about payment details. Search for the Send email action, then sign in to your Microsoft 365 account.

14. Fill in the message with the required fields.

15. Save the flow.

Trigger a Business Event
Power Automate can configure the application automatically for you. After you save your flow, it creates an endpoint, then it activates the business event for you. There is no remaining configuration step apart from verifying that the endpoint has been correctly configured before triggering an event.

1. Sign in to the client.

2. Go to System Administration > Setup > Business Events.

3. Select Endpoints.

4. Verify that a new endpoint has been created with a GUID appended in the name.

5. If you check the Active events tab, you can also verify that “Payment Posted” is activated for legal entity GBSI.

6. The final step is to trigger the business event of a posted customer payment and check whether the flow runs and you receive an email with customer payment details.

Troubleshooting a flow

Here are some troubleshooting suggestions:

- Power Automate provides a full history of runs to help determine what might be wrong with a failing flow.
- When reviewing a failed run, carefully review the inputs and outputs of trigger and action blocks.
- After changes have been made to the flow, go to the latest run or a particular run, and Resubmit the inputs to run the flow again.
This topic explains how to configure a Microsoft Azure Event Grid endpoint, and how to consume a business event from Event Grid.

**Scenario overview**

Security best practices recommend that you store connection strings outside applications, in an Azure Key Vault drive, and that you give applications the correct access to the key vault keys, secrets, or certificates.

Here are two of the many benefits of this approach:

- Someone who gets access to the application database won’t be able to get the third-party connection string.
- Maintenance is easier, especially when multiple applications access the same resources, because you must update connection strings in only one place.

Here is an overview of the procedures that you must complete:

1. Create a new event grid topic.
2. Create a new key vault to store the key for the event grid topic.
3. Register an Azure app that has permission to access the key vault.
4. Configure the parameters of the endpoint.
5. Consume the business event.

**Procedure 1: Create a new event grid topic**

1. Sign in to the Azure portal.
2. Select All services > Integration > Event Grid Topics.
3. Select Add to create a new event grid topic. Set the parameters, and then select Create. You can create a new resource group as a container for your lab, or you can use an existing resource group.
4. After deployment is completed, select the new event grid. On the property blade, select Overview, and make a note of the Topic Endpoint value. You will need this value later.
5. Back on the property blade, select Access keys, and copy the Key 1 value. You will need this value when you configure the key vault in the next procedure.
Procedure 2: Create a key vault

In this procedure, you will create a key vault to store the key that you copied in the previous procedure. A key vault is a secure drive that is used to store keys, secrets, and certificates. Instead of storing the connection string, a more typical and more secure approach is to store it in a key vault. You can then register a new application with Azure Active Directory (Azure AD) and grant it the right to retrieve the secret from the key vault.

1. In the Azure portal, select All services > Security > Key vaults.

2. Create a new key vault in your resource group and set the default parameters.

3. Select Overview, then copy and save the DNS Name value for the key vault. You will use this value later.

4. Select BE-key vault > Secrets > Generate/Import. Enter a name for your secret, and paste the event grid connection string that you saved earlier.
5. Select **Create**.

**Procedure 3: Register a new application**

In this procedure, you will register a new application with Azure AD, and give it read and retrieve access to key vault secrets. The application will then use this application to retrieve event grid secrets.

1. In the Azure portal, select **All services > Security > Azure Active Directory**.
2. Select **App registrations (preview) > New registration**, and then enter a name for your application.
3. Select **Register**.
4. Select your new application, and then select **Certificates & secrets > New client secret**. Enter a name for your secret, and set the secret so that it never expires. Then select **Add**.

5. Copy and save your new secret. You will use it later.

**IMPORTANT**

Secrets are visible only one time. If you forget to copy the secret, you will have to delete it and create a new secret.

6. Select **Overview**, and copy and save the application ID. You will use this value later.
Procedure 4: Configure a Business Events endpoint

1. Sign in to the application and go to System administration > Setup > Business events.
2. Select Endpoints.
4. Select Azure Event Grid.
5. Select Next.
6. Set the required parameter values.

7. Select All services > Security > Key vaults.

8. Select the key vault that you created earlier, and then select Access policies > Add new.

9. On the Principal blade, select your new registered application. Select the check boxes for the Get and List secret permissions to retrieve key vault secrets.

10. Save your new access policy.
Procedure 5: Consume a business event

The business scenario involves sending an email message whenever a free text invoice is posted for the USMF company. The message must contain details such as the customer account number, the customer name, and the total amount of the invoice.

1. Select the business event catalog and look for free text invoice posted business event.

2. Then activate the business event for USMF company. Once activated, a test message is sent to validate the configuration and cache the connection.

3. To verify that the test message has been received, in the Azure portal, select your event grid topic, and then select Metrics. Verify that both the Published Events metric and the Unmatched Events metric show a value of at least 1. If they don’t, wait for the batch job to pick up your message.

When both metrics have a value of at least 1, you will create a new logic app to subscribe to your event grid topic.

4. Select All services > Integration > Logic Apps.
5. Create a new logic app in your resource group.

6. After your logic app resource has been created, select the option to create a blank logic app.

7. Search for Event Grid, and select the When a resource event occurs (preview) trigger.

8. Select your subscription, select Microsoft.EventGrid.Topics as the resource type, and select the name of the event grid topic that you created in procedure 1.

9. Select New Step to add a new action.

10. Search for the Parse Json data operation. This step is required so that the message can be parsed by using the provided schema for the data contract.

11. Click in the Content field of the Parse Json action. The pane that appears gives you the option form the previous trigger. You must select the Data object field of the event grid message that contains the
payload that is transmitted by Finance and Operations.

Next, you must enter the provided schema for the contract. This is only a sample payload. However, you can use a capability of Azure Logic Apps to generate a schema from a payload.

12. Select your event in the business event catalog, and then select the **Download schema** link. A text file is downloaded. Open the text file, and copy the contents.

13. Go back to Logic Apps, and select the **Use sample payload to generate schema** link. Paste the contents of the text file, and then select **Done**.

14. Depending on the quality of your sample payload, your generator won't be able to distinguish between an integer and a real value, especially if the real value is provided as a whole number in the sample payload. Review the schema that is generated, and determine whether you must change a field of the integer data type to the number data type. (In JavaScript Object Notation [JSON], the number data type represents real values.)

Next, you will select a final action, such as sending a notification email that includes customer payment.
15. Search for the send email action, and then sign in to your Microsoft 365 account.

16. Fill in the message with the required fields.

17. Save your logic app.

18. Trigger the business event by posting a customer payment. Then verify that the logic app runs, and that you receive an email that includes customer payment details.
This topic explains how to configure a Microsoft Azure Service Bus endpoint and how to consume a business event from Service Bus.

Scenario overview

Security best practices recommend that you store connection strings outside applications, in an Azure Key Vault drive, and that you give applications the correct access to the key vault keys, secrets, or certificates.

Here are two of the many benefits of this approach:

- Someone who gets access to the application database won't be able to get the third-party connection string.
- Maintenance is easier, especially when multiple applications access the same resources, because you must update connection strings in only one place.

Here is an overview of the procedures that you must complete:

1. Create a new Service Bus namespace.
2. Create a new Service Bus topic and subscription.
3. Create a new key vault to store the Service Bus key.
4. Register an Azure app that has permission to access the key vault.
5. Configure a Business Events endpoint.
6. Consume the business event.

Create a new Service Bus namespace

1. Sign in to the Azure portal.
2. Select All services > Integration > Service Bus.
3. Select Add to create a new Service Bus namespace, and set the parameters. Select the Standard pricing tier. You can create a new resource group as a container for your lab, or you can use an existing resource group.

   **NOTE**
   
   If you select the Basic pricing tier, you can create only queues. To create topics, you must select the Standard pricing tier.

4. When you've finished setting all the parameters, select Create.

Create a new Service Bus topic and subscription

1. In the Azure portal, select the Service Bus that you just created, and then create a new topic.
2. Select the new topic, and then create a new subscription that is named **BE-USMF**.

3. Go back to the blade for your Service Bus, and create a new shared access policy to send events. Only the **Send** policy is required to send events to the Service Bus topic.

4. Select the new **Send** policy, and then copy and save the **Primary Connection String** value. You will use this value later.
Create a new key vault

In this procedure, you will create a key vault to store the key that you copied in the previous procedure. A key vault is a secure drive that is used to store keys, secrets, and certificates. Instead of storing the connection string, a more typical and more secure approach is to store it in a key vault. You can then register a new application with Azure Active Directory (Azure AD) and grant it the right to retrieve the secret from the key vault.

1. In the Azure portal, select All services > Security > Key vaults.

2. Create a new key vault in your resource group and set the default parameters.

3. Select Overview, then copy and save the DNS Name value for the key vault. You will use this value later.

4. Select BE-key vault > Secrets > Generate/Import. Enter a name for your secret, and paste the Service Bus connection string that you saved earlier.
5. Select Create.

Register a new application

In this procedure, you will register a new application with Azure AD, and give it read and retrieve access to key vault secrets. Finance and Operations will then use this application to retrieve Service Bus secrets.

1. In the Azure portal, select **All services > Security > Azure Active Directory**.

2. Select **App registrations (preview) > New registration**, and enter a name for your application.

3. Select **Register**.

4. Select the new application, and then select **Certificates & secrets > New client secret**. Enter a name for your secret, and set the secret so that it never expires. Then select **Add**.

5. Copy and save your new secret. You will use it later.

**IMPORTANT**

Secrets are visible only one time. If you forget to copy the secret, you will have to delete it and create a new secret.

6. Select **Overview**, and copy and save the application ID. You will use this value later.
7. Select All services > Security > Key vaults.

8. Select the key vault that you created earlier, and then select Access policies > Add new.

9. On the Principal blade, select your new registered application. Select the check boxes for the Get and List secret permissions to retrieve key vault secrets.

10. Save your new access policy.

**Configure a Business Events endpoint**

1. Sign in to the application and go to System administration > Setup > Business events.

2. Select Endpoints.

5. Select Next.

6. Set the required parameter values.
The business scenario involves sending an email or a message to a team channel whenever a customer payment is posted for the USMF company. The message must contain details such as the customer account number, the customer name, and the amount of the payment.

1. Select the business event catalog and look for **customer payment posted** business event.
2. Activate the business event for USMF company.

After you activate a business event that uses the new Service Bus endpoint, the application sends a test message to verify that the configuration is accurate and to cache the connection.

3. To verify that the test message has been received, in the Azure portal, select your **BE-Topic** Service Bus topic, and then go into the **BE-USMF** Service Bus subscription that you created earlier. Verify that the message count for the subscription shows a value of at least 1. If it doesn’t, wait for the batch job to pick up your message.
4. Select **All services > Integration > Logic Apps**.

5. Create a new logic app in your resource group.

6. After your Logic Apps resource has been created, select the option to create a blank logic app.

7. Search for **Service Bus**, and select it.

8. Select the trigger that is named **When a message is received in a topic subscription (auto-complete)**.

   **NOTE**
   
   Auto-complete means that the message is deleted from the subscription queue after it's retrieved. Peek-lock authorizes concurrent consumers. It requires a call to the `complete` command of the Service Bus application programming interface (API) in order to delete the message.

Because Logic Apps is accessing your Service Bus for the first time, it asks for a new connection. This connection will cache connection details as a Service Bus namespace URL and credential.

9. Select your Service Bus namespace, and enter a name for the new connection.

10. Select the **RootManageSharedAccessKey** policy for your logic app, and then select **Create**.

   **NOTE**
   
   The **Send** policy can't be used here, because you want to **retrieve** messages, not send them. As a best practice, you could have created a new policy for this use case and given it **Listen** permission only.
11. Select your trigger parameters. Be sure to use the correct names for the topic and subscription that you created.

This API polls Service Bus for new messages at a configurable recurrence (by default, every three minutes). If the volume of messages is low, the API will have a cost impact for unnecessary triggers, because Logic Apps is priced per trigger call and action run. However, you can implement a push architecture that uses Azure Event Grid in the middle. Service Bus can then push events to Event Grid when there are messages in a queue or a subscription. For more information, see Azure Service Bus to Event Grid integration overview.

12. Select New step to add a new action.

13. Search for the Parse Json data operation. This step is required so that the message can be parsed by using the schema of the data contract.

The body content that is received from the Service Bus is encoded into base64 format. Therefore, you must transform it to string format before the JavaScript Object Notation (JSON) payload can be parsed.

14. Click in the Content field, and then, in the pane that appears, on the Expression tab, enter the following expression: `Base64ToString()`
15. Put the cursor between the parentheses in the expression, and then, on the Dynamic content tab, find and select the Content of the message content from the previous Service Bus trigger. Then select OK.

Next, you must enter the schema of the contract that is received from the application. The application only provides a sample payload. However, you can use a capability of Azure Logic Apps to generate a schema from a payload.

16. Select your event in the business event catalog, and then select the Download schema link. Open the text file that is downloaded, and copy the contents.

17. Go back to your Logic Apps, and select the Use sample payload to generate schema link. Paste the contents of the text file, and then select Done.

18. Depending on the quality of your sample payload, your generator won't be able to distinguish between
an integer and a real value, especially if the real value is provided as a whole number in the sample payload. Review the schema that is generated, and determine whether you must change a field of the integer data type to the number data type. (In JSON, the number data type represents real values.)

Next, you will select a final action, such as sending a notification email that includes customer payment details.

19. Search for the send email action, and then sign in to your Microsoft 365 account.

20. Fill in the message with the required fields.

21. Save your logic app.

22. Trigger the business event by posting a customer payment. Then verify that the logic app runs, and that you receive an email that includes customer payment details.
This topic explains how to configure a Microsoft Azure Service Bus Queue endpoint.

Create an Azure Service Bus Queue endpoint

1. On the Business events page, on the Endpoints tab, select New to create an endpoint.
2. In the Configure new endpoint dialog box, in the Endpoint type field, select the appropriate endpoint type. To create an endpoint to a Service Bus queue, select Azure Service Bus Queue.
3. Select Next.
4. In the Endpoint name field, enter the name of the endpoint.
5. Set up Azure Key Vault to provide the secret to the Azure messaging resource.
6. Set up the Azure Active Directory (Azure AD) application ID and application secret.
7. Back in the Configure new endpoint dialog box, in the Queue name field, enter the name that you created for the Service Bus queue in the Azure Service Bus Queue configuration in Azure.
8. In the Azure Active Directory application ID field, enter the application ID that you created in Azure AD in the Azure portal.
9. In the Azure application secret field, enter the secret value for the application.

10. In the Key Vault DNS name field, enter the Domain Name System (DNS) name from your Key Vault setup.

11. In the Key Vault secret name field, enter the secret name for the endpoint resource that must be created in Key Vault.

The Key Vault Secret value in Azure will be the Primary Connection String value for the Service Bus. You can find this value in the Service Bus that you configured, at Shared Access Policies > RootManagedSharedAccessKey.
12. Select OK.

**IMPORTANT**

The Azure application that was registered must be also added to the Key Vault setup under Access policies in the key vault. To complete this setup, select the Key, Secret & Certificate Management template, and then select the application as the principal.
This topic explains how to use Microsoft Power Automate to configure and consume a workflow business event for purchase requisition approval.

To complete this topic, you must be running Microsoft Dynamics 365 for Finance and Operations version 10.0.2 (May 2019) with platform update 26 or later.

Scenario overview

The following illustration shows the high-level process that you must configure by using Power Automate. Note the following points:

1. The application fires a business event whenever a new approval starts.
2. Power Automate trigger starts.
3. After parsing business event payload from F&O, next step is to check whether the workflow instance ID received from F&O is still alive. This is a security step in case approval has already taken place or workflow has been recalled.
4. If the check is unsuccessful, an email is sent to notify the user about a potential work item in their workspace.
5. If the check is successful, a new Power Automate approval is started.
6. Then workflow is completed by using the outcome of the approval. The outcome can be either Approve or Reject.

Exercise 1: Create a new flow

1. Sign in to the Power Automate portal.
2. Select an existing environment where you have the right to create a flow resource. The (default) environment is available to all companies.
3. Select New > Create from blank.
4. Search for Dynamics 365 for Finance and Operations, and select the connector.
5. A new trigger is created. This trigger is named When a Business Event occurs. Select it.
6. Select the environment instance that has these characteristics:
   - The category is Workflow workitem.
• The event name is **Purchase requisition review (000062) – Approve purchase requisitions**.
• Any legal entity is selected.

7. Select **New Step** to add a new action.

8. Search for the **Parse Json** data operation. This step is required so that the message can be parsed by using the schema of the data contract that the application provides.

9. Select the content field of the **Parse Json** action. The **Body** output from the previous step should appear as an option. Select **Body**.

    Next, you must enter the schema of the contract. The application provides only a sample payload. However, you can use a capability of Microsoft Flow to generate a schema from a payload.

10. Select the **000062** workflow event in the catalog, and then select the **Download schema** link. Open the text file that is downloaded, and copy the contents.

11. Go back to Power Automate, and select the **Use sample payload to generate schema** link. Paste the contents of the text file, and then select **Done**.

12. Add a new step to call a workflow action that validates whether a workflow that has the correct instance ID is running and awaiting approval.

13. Add a new condition control step to check the result of the validate action. The dynamic field won't provide the required output. Therefore, you must manually enter the following expression instead: **Body('Execute_action')?['value']**. Then select **OK**.

14. The condition control automatically creates two branches for **Yes/No** results. If the result of the validate step is **No**, an email must be sent to the user. This email notifies the user that a new task requires
attention, and that the user must sign in to the client. In order to complete this step create a new send email action within the No container and fill in the parameter with the email of the Approver from the previous step workflowuseremail and a subject and body of your choice.

NOTE
The email address that the workflow business event returns is the email address of the workflow approver. If the workflow approver user hasn't been configured in your demo environment, you can use your own email address for demo purposes.

15. If the result of the validate step is Yes, you must start a new Power Automate approval step. In the Yes container, select a new action that is named Start and wait for an approval (v2), and choose inputs as follows: Approval type: Approve/reject: first to respond title: workflowworkitemsubject output form Business event payload Assigned to: workflowuseremail output Then you can fill in the details section with as much information as needed from previous step such as workflowdocument or workflowstepinstruction. Again, you can use your own email address in the Assigned to field for demo purposes especially if the workflow approver user hasn't been configured in your demo environment.
16. Next, you must complete the workflow approval by using the outcome of the approval step. Still in the **Yes** container, add a new **Finance and Operations Execute Action** step, and choose the **WorkflowWorkItem-complete** action and the **WorkflowWorkItemInstanceID** parameter. Then fill in the rest of the parameters from the approval outputs. As a minimum the outcome section with Approval outcome and the comment section with the approver’s responses. Because the approval step can support multiple approvers, the response output is an array. Therefore, as soon as you select the output **Responses** as an input for the comment section, Power Automate automatically embeds your action in an **Apply to each** container as shown below.
Exercise 2: Trigger a business event

Power Automate can automatically configure the application for you. After you save your flow, Power Automate creates an endpoint and activates the business event. You don't have to complete any other configurations. You just have to verify that the endpoint has been correctly configured and then trigger an event.

1. Sign in to the client.
2. Go to System administration > Setup > Business events.
3. Select Business events.
4. Select Endpoints.
5. Verify that a new endpoint has been created, and that a globally unique identifier (GUID) has been appended to the name.
6. On the Active events tab, verify that Workflow workitem is activated for the USMF company.
This topic goes through a scenario where Microsoft Forms Pro is used to create a survey that can be used with business events. Specifically, in the scenario that is described here, a survey is sent to customers when a product has been shipped. The survey information is gathered by using Forms Pro.

**Prerequisites**

If you haven't used Forms Pro before, you should first read the [Forms Pro documentation](https://docs.microsoft.com/en-us/microsoft Forms) to learn how to use it.

**Scenario**

1. Create a survey. Based on the title that you enter for the survey, Forms Pro suggests survey questions.

   ![Customer Satisfaction Survey](image)

   - **Overall, how satisfied are you with our company?**
   - **Please explain your satisfaction level in the question above.**
   - **How well do our products meet your needs?**
   - **How would you rate the value for money of the product?**
   - **How responsive have we been to your questions or concerns about our products?**
   - **How long has your organization been a customer of our company?**
   - **How likely are you to continue doing business with us in the future?**
   - **How likely are you to recommend our company to a friend or colleague?**
   - **Please share any additional comments or questions:**

2. The sales order tracks the shipment. When the product has been shipped, the status of the sales order is changed to **Delivered**.
Therefore, configure an alert on the sales order, so that an alert is created whenever the value of the Status field is changed. Be sure to set the Send externally option to Yes, so that the alert will be sent out as a business event.

3. Set up the flow that will be triggered by the business event whenever the status of the sales order is updated (see the illustration in the next step). After it’s triggered, the flow will use the Forms connector to send the survey to the customer email address that is registered on the sales order.

The customer email address and other information that is required for the scenario must be in the payload of the business event. If the payload doesn’t have this data, it can be extended so that it includes the appropriate fields. For more information, see the Business events developer documentation.

4. Because Microsoft Power Automate is used to orchestrate this scenario, don’t activate the When a change based alert occurs business event in the application. Instead, set up Power Automate so that it subscribes directly to the business event.
5. After you’ve finished setting up the flow, it will be triggered and send out the survey whenever the sales order’s status is updated.

As users fill in the survey and submit it, Forms Pro shows some analytics.
100% of responders have expressed Positive sentiment.
This tutorial describes the steps that you must follow to make business events work with Microsoft Azure Event Hubs.

1. In Azure portal, create an Active Directory application registration. Make a note of the application ID.

2. Give the app, permission to the Azure Key Vault application programming interface (API).

   **API permissions**: Applications are authorized to use APIs by requesting permissions. These permissions show up during the consent process where users grant/deny access.

<table>
<thead>
<tr>
<th>API / PERMISSIONS NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Azure Key Vault (1)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>user_impersonation</td>
<td>Delegated</td>
<td>Have full access to the Azure Key Vault service</td>
</tr>
<tr>
<td>Microsoft Graph (1)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>User.Read</td>
<td>Delegated</td>
<td>Sign in and read user profile</td>
</tr>
</tbody>
</table>

3. In the app registration, create an application secret. Make a note of the value.

   Credentials enable applications to identify themselves to the authentication service when receiving tokens at a web addressable location (using an HTTPS scheme). For a higher level of assurance, we recommend using a certificate (instead of a client secret) as a credential.

   **Certificates**
   Certificates can be used as secrets to prove the application's identity when requesting a token. Also can be referred to as public keys.

   No certificates have been added for this application.

   **Client secrets**
   A secret string that the application uses to prove its identity when requesting a token. Also can be referred to as application password.

<table>
<thead>
<tr>
<th>DESCRIPTION</th>
<th>EXPIRES</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>vaultAppSecret</td>
<td>12/01/2030</td>
<td>My************</td>
</tr>
</tbody>
</table>

4. In the key vault, give permission to the new app registration.
5. In the key vault, create a new secret. The value of this secret must be the connection string to your event hub. Make a note of the value.

6. Create an endpoint configuration for the event hub. Go to System administration > Setup > Business events > Business events catalog, and then, on the Endpoints tab, select New to open the Configure new endpoint wizard.
7. In the **Endpoint type** field, select **Azure Event Hub**.

8. Select **Next**.

9. In the **Endpoint name** field, enter a name for the endpoint.

10. In the **Hub name** field, enter the name of your event hub.

11. In the **Azure Active Directory application ID** field, enter the application ID that was created earlier.

12. In the **Azure application secret** field, enter the value that was created earlier.

13. In the **Key Vault DNS name** field, enter the Domain Name System (DNS) name of your key vault. You can find this value on the **Overview** tab of the key vault configuration in the Azure portal.

14. In the **Key Vault secret name** field, enter the name from the secret that was created earlier.

15. Select **OK**.

16. You can now activate one or more business events that should be sent to this endpoint.
IMPORTANT

Before you subscribe to Finance and Operations apps business events and data events in Microsoft Dataverse, you must enable the Microsoft Power Platform integration. For information about how to enable the Microsoft Power Platform integration for a Finance and Operations apps environment, see Enabling the Power Platform integration.

You can subscribe to Finance and Operations apps business events and data events in Dataverse by registering plug-ins and software development kit (SDK) steps on the events in Dataverse. This topic describes how to use the Power Platform Tools extension for Visual Studio to register a plug-in for a Finance and Operations apps event. The subscriptions are shown together with other subscriptions in the business event catalog in Finance and Operations apps. The endpoint then works like other endpoints in the Finance and Operations apps business event catalog.

Set up your development environment

Install the Power Platform Tools extension

Power Platform Tools for Visual Studio is an extension that provides code templates for Dataverse plug-ins. It includes a Dataverse explorer that shows tables, business events, and virtual entity data events. The explorer lets you register plug-ins directly from Visual Studio. The C# code for the plug-in can then be deployed directly to Dataverse from the solution.

For information about how to install the Power Platform Tools extension, see Install Power Platform Tools.

Create a project

After you've installed the Power Platform Tools extension, create a new project.

1. Open Visual Studio 2019 or later.
2. In the Get started dialog box, select Create a new project.
3. In the Create a new project dialog box, search for Power Platform Solution Template, select it, and then select Next.
4. In the **Configure your new project** dialog box, enter a project name, select the location where you want to save the solution file, and then select **Create**.

5. In the **Configure Microsoft Power Platform Solution** dialog box, under 1. **Solution Type to Configure**, select **Start from Dataverse**.

6. In the **Power Platform Tools** dialog box, under 2. **Connect to Dataverse**, follow these steps:
   
a. In the Deployment Type field group, select the **Office 365** option.
b. Select the Display list of available organizations checkbox.
c. Select **Login**, and enter the credentials to sign in to the Dataverse environment that is linked to your Finance and Operations apps environment.
d. In the list of organizations, select the Microsoft Power Platform environment that you want to work with. Then select **Login**.
e. Select **Next**.
7. Under **Select Solution**, select the Microsoft Power Platform solution where you want to create the event subscription. If you haven’t yet created a solution, you can create one in the Power Apps maker portal by following the steps in **Create a solution**.

8. Select **Done**.

9. In the **Visual Studio Template Selection Microsoft Power Platform** dialog box, under **1. Select**
Items for Template, select Add New Templates.

10. In the Create New Items dialog box, under 2. Selected Template Projects, select the Add Plugin Project checkbox, and then select Next.

11. Under 3. Assign project Names, in the Plugins field, enter a name for the plug-in project. The name will be the name of the Visual Studio project. By default, it will also be the name of the assembly.

12. Select Done.

For more information about how to use the Power Platform Tools extension to create a project, see Quickstart:
Create a Power Platform Tools project.

Sign the assemblies
Dataverse assemblies must be signed. You can either set up a self-signed key in the solution or provide another key if you have one available. To create a self-signed key, follow these steps.

1. In Visual Studio, in Solution Explorer, select and hold (or right-click) the project name, and then select Properties.
2. On the Signing tab, select the Sign the assembly checkbox.
3. In the Choose a strong name key file field, select New.
4. Enter a name and password for the key, and then select OK.

Subscribe to a Finance and Operations apps event
After you've finished setting up the development environment, you can begin to write code. You can create a C# class library that runs business logic in Dataverse when a Finance and Operations apps business event or data event that the plug-in is subscribed to occurs.

Register a new step
1. In Visual Studio, on the View menu, select Power Platform Explorer.

   Power Platform Explorer shows a list of components from the Dataverse environment that you selected during the setup of the development environment. These components include tables, choices, and event catalogs.

2. Under the Event Catalog node, expand Finance and Operations.

   Under the Finance and Operations node, you should see a list of catalogs that are available in the Dynamics 365 ERP Virtual Entities solution in the selected Microsoft Power Platform environment. Under each catalog, you should see a list of the virtual entities that have been generated for that category in the environment, and the data events that are available for each of those virtual entities (Created, Updated, and Deleted).

   (If you don't see any catalogs under the Finance and Operations node, you might have to generate and enable the virtual entities that are required for your solution. For more information about how to generate virtual entities in a Dataverse environment, see Enable Microsoft Dataverse virtual entities. After you've enabled the required virtual entities, select Refresh in Power Platform Explorer to update the list so that it shows the entities.)

   Under each catalog, under the Global node, you should see all the Finance and Operations apps business events that have been activated for the category.

3. Select and hold (or right-click) the data event under the virtual entity that should trigger your business logic, and then select Add Plugin.
4. In the Register New Step dialog box, follow these steps:

   a. In the Class Name field, change the value to the name of the class that you want to create.
   b. Under Event Pipeline Stage of Execution, select PostOperation in the drop-down list.
   c. Under Execution Mode, select the Asynchronous option.
   d. Select Register New Step.

   **NOTE**

   The PreValidation and PreOperation execution stages and the Synchronous execution mode aren’t currently supported for virtual entities.

When the new step is registered, a new class is generated that has the base code for the plug-in. In the **ExecuteCdsPlugin** method of the new class, you can write the custom business logic in the place that is indicated by the **TODO**. You can then build your solution and deploy the plug-in to your environment.
Deploy the plug-in

You can now deploy your plug-in to the Microsoft Power Platform solution.

- In Visual Studio, in Solution Explorer, select and hold (or right-click) the project, and then select Deploy.

To verify that deployment was successful, you can view the plug-in assembly in the Power Apps maker portal. Go to the Microsoft Power Platform solution that you deployed the plug-in to, and then, in the navigation on the left, select Plug-in assemblies. To view the registered plug-in step, select Plug-in steps in the navigation.

You can also verify that the new endpoint appears correctly on the Endpoints tab of the Business events page in the Finance and Operations app, and that the new event appears on the Active events tab.

Troubleshooting

If deployment fails, you can troubleshoot the issue by turning on verbose logging.

1. In Visual Studio, on the Tools menu, select Options.
2. In the Options dialog box, under the Power Platform Tools node, select General.
3. Select Display Detailed Log Data and (Diagnostics) Capture Detailed Dataverse Communications Log.

4. Select OK.
This topic explains how to use business events in the financial period close business process to gain insights and provide internal controls.

To complete this topic, you must be running version 10.0.2 (May 2019) with Platform update 26 or later.

Scenario overview

Task management is fundamental to managing business processes across industries. Out-of-box capabilities let users manage business process tasks in a structured manner. The Financial period close workspace illustrates these capabilities by offering a central location for managing tasks in a company’s accounting period close process.

This topic looks at an organization that recently decided to explore how it can use the Financial period close workspace to track and report tasks that are associated with every period close. Performance management and traceability are some of the challenges that this organization faces in the current setup. Therefore, the organization undertook an exercise in business process transformation to identify the capabilities of the Financial period close workspace. This exercise revealed the following business requirements:

1. The ability to be notified when tasks must be started
2. The ability to attach documents
3. Record management and disposition capabilities for attachments
4. The ability for multiple approvers to approve tasks, based on predefined logic
5. Task questionnaires for audits
6. Reporting capabilities to track the current status of the period close process and do performance analysis for insights into efficiency

High-level design

To achieve the previously mentioned requirements, the organization used out-of-box capabilities of the Financial period close workspace. A gap analysis revealed that, by doing minor extensions to the workspace and the underlying data entities, the organization could achieve requirements 2, 5, and 6, and could partially achieve requirement 4. To achieve requirements 1 and 3, and parts of requirement 4, the organization chose to use Power Automate. The following illustration shows an architectural overview of the solution.
Managing attachments by using Microsoft Power Automate and SharePoint Online

Accountants view their tasks in the Financial period close workspace and start to work on them. Attachments are added to the task by using a SharePoint Online document type. SharePoint triggers in Microsoft Power Automate are used to trigger the Power Automate that is shown in the following illustration. This Power Automate updates the SharePoint metadata with metadata from the task in the Financial period close workspace. SharePoint columns were created for this purpose in the document library. A separate attachment data entity was created to hold the attachment metadata for every attachment that is added to the Financial period close workspace. Fields from the custom entity were mapped to the SharePoint Online columns in the Power Automate. When documents that use the specified document type are created in the predefined SharePoint Online library, Power Automate is triggered, obtains the metadata from the custom data entity, and updates the document's metadata columns in SharePoint Online.

Enabling internal controls by using business events and Power Automate

As accountants complete their tasks, and the tasks become ready for review, the value of the Review status custom field is updated to Ready for review. The Power Automate gets triggered by the When the change-based alert is triggered business event when this update is made. The payload of this business event contains the task name and the area name. The Power Automate uses the combination of the task name and area name, together with the value of the Review status field, to route the task through an email-based workflow that is orchestrated by Power Automate. The Power Automate waits for approval, add new comments to the task log, and updates the task in the Financial period close workspace, based on both the outcome of the approval process and related metadata. Custom data entities were built in to query and update the Financial period close workspace by using Power Automate.

Subscribing to the business event

The following example describes the general steps for subscribing to a change-based alert business event.

1. Add the connector trigger to the Power Automate app, and subscribe to the change-based alert business event.
2. Parse the business event payload.

When the business event is triggered, it triggers Power Automate. This business event contains a payload. In this step, the payload is parsed, and the required variables are initialized.

3. Retrieve the task, based on the values from the payload.

When the task is updated, the business event triggers Power Automate. At that point, after the payload has been parsed, you will know basic information about the task. In this step, the custom data entity is used to retrieve more information about the task.
4. Retrieve approvers from the Microsoft Excel file, based on the criteria.

Next, you must determine the list of approvers, so that you can send the approval request in the appropriate manner. This list is a custom Excel file in a SharePoint Online library. In this step, you query the Excel file to get the list of approvers. You also get the links to the attachments for each task, so that you can send the attachments to the approvers.

5. Prepare to send the request for approval.

In this step, you prepare Power Automate to send the approval request by using all the information that was gathered and assembled in the previous step.
6. Start the approval process.

In this step, the approval request is sent from Power Automate.
7. Process the approval action that is taken by approvers.

After the approvers receive the approval request and take action, the Power Automate is notified, and additional processing is done.

8. Update the task with the approval outcome.

Based on the outcome of the approval process, the task is updated with the result.
Conclusion

For the business requirements of the organization that is described in this topic, this solution involves minimal development and relies mostly on the Financial period close workspace, business events, SharePoint Online, and Power Automate to drive functionality. Development is restricted to the addition of fields to pages, the creation of custom data entities, and changes to page labels. Power Automate also provides greater flexibility in the approval process. Because the solution takes advantage of the various applications in the Microsoft 365 suite, internal users can use applications that they are already familiar with. Therefore, the amount of change management that is required is limited.

In conclusion, business events offer unique opportunities for extending functionality but also let you avoid extensive in-app customizations. Here are some things to consider before you start to use business events:

- Establish the security requirements of your solution. Business events honor role-based security. This behavior
can be beneficial in some use cases.

- Business events functionality continues to get enhanced. Be on the lookout for new capabilities.

Business events and Power Automate offer great opportunities for implementing low-code or no-code extensions. The important thing is that you identify opportunities where this framework can help, but that you also understand some of the limitations.
Add-ins provide a way to extend the functionality of Finance and Operations apps. All add-ins are installed and managed via the environment details page for sandbox and production environments in Microsoft Dynamics Lifecycle Services (LCS). For more information about the architecture and how to unlock this feature, see Microsoft Power Platform integration with Finance and Operations apps.

What add-ins are available?

New add-ins are made available on a regular basis. This section describes the add-ins that are currently available and provides links to more information about each.

**Planning Optimization**
The Planning Optimization Add-in for Microsoft Dynamics 365 Supply Chain Management enables master planning calculation to occur outside Dynamics 365 Supply Chain Management and the related SQL database. The benefits that are associated with the Planning Optimization functionality include improved performance and minimal impact on the SQL database during master planning runs. Quick planning runs can be done even during office hours. Therefore, planners can immediately react to demand or parameter changes. To learn more, see Planning Optimization overview.

**Inventory Visibility**
The Inventory Visibility Add-in is an independent and highly scalable microservice that enables real-time tracking of on-hand inventory. Therefore, it provides a global view of inventory visibility. To learn more, see Inventory Visibility Add-in.

**Export to Azure Data Lake**
The Export to Azure Data Lake feature is based on a microservice that exports Finance and Operations app data to Azure Data Lake and keeps the data fresh. To learn more, see Configure export to Azure Data Lake.

**IoT Intelligence**
IoT Intelligence is an add-in for Supply Chain Management. It integrates Internet of Things (IoT) signals with data in Supply Chain Management to produce actionable insights. To learn more, see IoT Intelligence home page.
By using mobile apps, you can reuse business logic and modeling. Mobile apps enable rich offline and mobile interactions, and provide an easy-to-use designer experience. Developers can create simplified forms in Microsoft Visual Studio and then design mobile apps that expose this functionality. The mobile platform makes it easy to change the forms and mobile app definitions to include customizations that are made to your cloud app.

Get started

- Getting started
- Architecture
- Page design guidelines
- Action design guidelines
- Form design requirements

Check out the following series of how-to videos that show how to create a mobile app.

- Tutorial 1: Building the sales order page
- Tutorial 2: Building the sales order details page
- Tutorial 3: Building the create new sales order action
- Tutorial 4: Adding a lookup to the create new sales order action
- Tutorial 5: Adding a lookup and hiding pages using mobile business logic

Common configurations

These topics describe some common customizations that you can add to your mobile app.

- Localize mobile workspaces
- Help secure mobile workspaces
- Set up clickable fields
- Set up mandatory fields through workspace classes
- Display item counts in a field

Client-side development

Client-side APIs are used in the business logic file, which provides an extensibility layer to the mobile workspace that allows for customization. Some things that you can access and influence through the client-side APIs include:

- Metadata
- Runtime control/page instances
- Business data
- Offline-first business behaviors
- Layout and style

The process for client-side development is described in these topics:

- Client-side design APIs overview
Business logic events overview

Client APIs

You can download a sample business logic file (with a .js file name extension) for the Reservation management workspace. Go to Dynamics365-for-Operations-mobile-FleetManagementSamples, open the business_logic folder, and locate the FM.js file.

Server-side development

Workspace attributes and classes are used to create, configure, and publish workspaces on the server. These server-side X++ APIs can be used instead of using the task recorder-based mechanism to build a workspace. Workspaces created using either mechanism can then be styled and augmented using the client-side APIs.

Server-side development is described in these topics:

- Workspace class overview
- Server APIs (X++)

You can download the sample project (with an .axpp file name extension) for the Fleet Management mobile app. Go to Dynamics365-for-Operations-mobile-FleetManagementSamples and download the FMMobileApp.axpp file.

Debugging during development

During development it can be useful to attach a debugger to get more detailed information and insight into what is happening in the background. A web debugger can be used with the client-side JavaScript logic and styling and the Visual Studio debugger can be used with the server-side X++ business logic.

Debugging the client side

Prerequisites

- Android device plus PC
- Azure-hosted development machine (so the mobile device can point to it)

Steps to debug the client side

1. On the web client that is exposed by the Azure-hosted development machine, ensure that there are mobile workspaces published for the Finance and Operations app. For information about publishing a mobile workspace, see Publish mobile workspaces.

2. Install the Android debug apk for the Finance and Operations app on an Android device:

   - One time only, allow the installation of apk files - Go to Menu > Settings > Security and then check Unknown Sources to allow the phone to install apps from sources other than the Google Play Store.
   - Uninstall the Finance and Operations app - Ensure that any previous version of the Finance and Operations app has been uninstalled.
   - Download the apk file - From the device's browser, navigate to the latest Finance and Operations Android debug apk on GitHub and click Download (or use this direct link to the file).
   - Install the Finance and Operations apk file - Confirm install of the Finance and Operations app via the apk file.
   - Run the debug Finance and Operations app on the device and sign in.

3. Connect to the device from the debugging machine.

   - On the Azure-hosted development machine or a separate PC, follow Android developer instructions to Get Started with Remote Debugging Android Devices. You can also find a wide selection of instructional videos on YouTube by searching for Chrome for Android remote debugging.

4. After you connect the debugger, find the active tab on your device. You may need to click View more
Debugging the server side

Prerequisites

Steps to debug the server side

1. On the web client exposed by the Azure-hosted development machine, ensure that there are mobile workspaces published for the Finance and Operations app. For information about publishing a mobile workspace, see Publish mobile workspaces.

2. Open the app on your device, point to the Azure-hosted development machine, and sign in.

3. Open Visual Studio on the Azure-hosted development machine and attach the debugger to the w3wp process.

4. After you connect the debugger, find the desired business logic, and insert breakpoints as needed.

5. Either use the app on your device as usual, or reflect the mobile device on your desktop so you can interact with it on the desktop screen.

6. Navigate through the desired workspace and forms.

5. Reflect the mobile device on your desktop so that you can interact with it on the desktop screen.

6. Go through the desired workspace and forms.

7. If breakpoints are encountered, then the browser developer tools will allow you to control the flow of execution and see the values and parameters being passed.

8. To change styling at runtime, use the elements tab to alter the styling. This will help you determine what elements JavaScript should target and how those elements should be styled.

9. If a needed change is identified, make those changes in JavaScript, and then push those changes into the environment.

10. If more changes or validation is needed, repeat the process.

**Debugging the server side**

**Prerequisites**

- Azure-hosted development machine (so the mobile device can point to it)

**Steps to debug the server side**

1. On the web client exposed by the Azure-hosted development machine, ensure that there are mobile workspaces published for the Finance and Operations app. For information about publishing a mobile workspace, see Publish mobile workspaces.

2. Open the app on your device, point to the Azure-hosted development machine, and sign in.

3. Open Visual Studio on the Azure-hosted development machine and attach the debugger to the w3wp process.

4. After you connect the debugger, find the desired business logic, and insert breakpoints as needed.

5. Either use the app on your device as usual, or reflect the mobile device on your desktop so you can interact with it on the desktop screen.

6. Navigate through the desired workspace and forms.
7. If breakpoints are encountered, then Visual Studio will allow you to control the flow of execution and see the values and parameters being passed.

8. If a needed change is identified, make those changes in X++, and push those changes into the environment.

9. If more changes or validation is needed, repeat the process.

Troubleshooting the app

[Resolved] - No support for iOS14 due to issues with date and time controls

Version 2.2.8 of the Finance and Operations mobile app fixes the known issues with the date and time pickers in iOS14. Ensure that you have the latest version of the app if you are experiencing issues running the application on iOS14.

The Mobile Client app is not working on particular devices

Sometimes the cache associated with the app becomes corrupt or obsolete and needs to be cleared. Unfortunately, the only way to clear the data associated with the app is to uninstall the app. To completely uninstall the app, don’t use the “long-press wiggle and x on the app icon” method. Instead, completely uninstall the app by navigating to Settings > General > iPhone Storage > Finance and Operations (Dynamics 365), and then click Delete App. After 10-15 seconds, the app can be reinstalled.

On Android devices with non-English regions, the comma can’t be used as the decimal separator in an amount field

On Android devices with non-English regions, using a comma as the decimal separator is standard practice. Problems using a comma in an amount field is an Android-specific problem because iPhone works as expected. On Android, use of the comma in an amount field is a problem with the default “gboard” keyboard and some other keyboards. Installing the SwiftKey keyboard (published by Microsoft) allows the entry of commas just like on iPhone: SwiftKey Keyboard.

Change needed for ADFS to support Mobile Client in on-premises environments

If Active Directory Federation Services (ADFS) is in use on the domain and the environment is on-premises, then ADFS must be configured to provide a regular forms-based authentication screen instead of using Windows Integrated Authentication (WIA). The Finance and Operations apps for iOS and Android require the regular forms-based authentication screen. ADFS should be configured to only provide WIA for browser clients (use cases). For more information, see Configure intranet forms based authentication for devices that do not support WIA.

Using multi-factor authentication with the Finance and Operations app

The Finance and Operations (Mobile Client) app facilitates user authentication with Azure Active Directory (Azure AD) by presenting the Azure AD sign-in web page within an embedded browser. After a successful sign in, it will retrieve the user token from the cookies and use that when communicating with the user interaction service that it shares with the web client. Some multi-factor authentication mechanisms that involve switching to a different app on the same device will cause the embedded browser to close, so the sign in will fail. The workarounds for this include:

- Different device - Use a different device for the multi-factor authentication response so the app remains active on the original device.
- Multi-factor authentication via phone call - Use a phone call for the multi-factor authentication response so an app switch is not needed.
- Use the “touch and hold” gesture on the authentication notification and then select the Accept option. Because the notification acceptance will not require an app switch, the sign in will proceed as usual.

If there are continued problems with MFA authentication, it is helpful to submit the Microsoft Authenticator app
logs and provide support with the resulting Incident ID.

Intune support and conditional access

The Finance and Operations (Mobile Client) app does not have Microsoft Intune policies implemented, so it does not support Intune. Manually adding the app (following Add iOS store apps to Microsoft Intune) is also not supported because the device identifier cannot be passed.

Trouble signing out of the app and signing in with new credentials

If you experience trouble signing out of the app and signing in with new credentials, then you might need to "forget old credentials" on the Azure AD sign-in screen.

- To sign out of the app, follow these steps:
  - Open the app.
  - Sign out of the app.
  - Force close the app.
- To forget old credentials, follow these steps:
  - Open the app.
  - Connect to the server.
  - On the Azure AD sign-in screen, if there are saved credentials, select the ellipsis (…) button on that card, and then select Forget the credential.
  - Force close the app.
- To sign in to the app, follow these steps:
  - Open the app.
  - Connect to the server
  - Sign in using the Azure AD sign-in screen.

Troubleshooting app content

I can't figure out how to build or change something in my Mobile Client content

There are many resources that you can leverage to figure out how to build or change content for the Mobile Client.

- Review the documentation provided in the Help system.
- Review the Fleet Management Samples for examples.
- Publish and review the Expense Management workspace, and other standard workspaces, for examples. Demo data for the USSI company is useful when using the Expense Management workspace. The forms and X++ code that make up the Expense Management workspace can be found in the Application Explorer by searching for the "ExpenseMobile" prefix.
- Leverage the Dynamics Community forums by searching for answers and asking questions when needed.

Tips for workspace creation and modification

Here are some tips for workspace creation and modification:

- Create new simplified forms for recording rather than recording large complex forms.
- After recording a form, you have to close the form instead of clicking Done, otherwise the form remains open.
- Verify that recordings are correct using the "Job steps".
- Play back recordings using task recorder playback to verify them.
- Don’t navigate to a page before starting the recording, because the context from the previous page might need to be captured.
- If you re-record a page with a grid then you need to re-record the link to the Details page because otherwise it won't be there.
- When recording an action, change the value of the fields to add them. When recording is complete, close the form instead of clicking **Save**.
- Lookups in mobile are list pages that have been recorded. **Select field data** and **Select field to display** are used to select the **field to use as the value to save** (data) and the **field to show the user** (display).
- When adding a lookup field, select a value in a lookup instead of just adding the lookup field. This will ensure that the correct value is selected.
- If you re-record a lookup, all the references also need to be re-recorded because the GUID for the lookup will change.
- If you want to add a field to a page, you need to add all the fields again, because the list is cleared at the beginning of each edit. This is a limitation of task recorder. Note that reordering is also not possible.
- In the workspace XML, GUIDs are used as references to forms and controls instead of names. GUIDs are used to ensure uniqueness, but this comes at the cost of maintainability. Those GUIDs are regenerated on each modification, so partial edits are very difficult. The use of GUIDs would be very costly to change, so it is unlikely that changes would be made in the future to use simpler string name references.
- Relationships between form datasources need to be via RecordId instead of string. For example, primary keys of the datasources should not be strings.
- Customers and partners can fork a workspace by creating a copy of it and then make changes as needed.
- There is no check box in mobile. You have to manually bind the field to a Yes/No enum in JavaScript.

**Common problems with form recordings**

Avoid using forms with these patterns and controls when creating workspace recordings:

- Datasources with DelayedJoin (common on transaction forms).
- FastTabs (common on existing forms).
  - Recorded forms should not have FastTabs because the FastTabs expansion state can interfere with playback.
- Any user interface (UI) that has state, like an expandable or hide/show region.
- There is no check box in mobile. You have to manually bind the field to a Yes/No enum in JavaScript.
After you acquire a development environment, complete the following procedures to get started with development.

**Get the Fleet Management mobile forms**

We have created new, purpose-built forms in the Fleet Management module. These forms are used specifically for the mobile app and aren’t meant to be used through the web client.

1. Download the file that contains the Fleet Management project (.axpp file).
2. Extract the contents of the zip file to a temporary location on the development computer.
3. Import the project (.axpp) file by using Microsoft Visual Studio (click Finance and Operations > Import Project).
4. After you've imported the project file, build the project or module.

**Get the sample workspace**

We provide a sample workspace for Reservation management. This workspace is based on the Fleet Management module.

1. Download the file that contains the sample workspace (.xml file).
2. Sign in to your non-production client. (You must sign in as an administrator.)
3. In the address bar, add &mode=mobile to the end of the URL, and then press Enter.
4. In the client, go to Settings > Mobile app. The mobile app designer will appear docked next to the client.
5. Click the Overflow button (…), and then click Import.
6. Click the Browse button that appears at the bottom of the page.
7. In the file selection dialog box that appears, select one of the XML files that you previously extracted from the zip file.
8. After the app has been loaded into the mobile app designer, click Done at the bottom of the page.
9. Click Publish workspace.

**Get the mobile app**

The mobile app is being made available for the most popular mobile operating systems. You must have a Dynamics 365 Unified Operations instance and valid user credentials in order to log in to the app.

- Android (available now) - Finance and Operations mobile app on the Google Play Store
- iPhone (available now) - Finance and Operations mobile app on the iTunes apps store

You’re done! Launch the app from your mobile device to see the sample workspace.

**Additional resources**

*Architecture*

*Client APIs reference*

*Server APIs reference*
The mobile app communicates with Application Object Server (AOS) to get the metadata for the mobile workspaces (and the pages and the fields that appear on the page), and to get the data for the fields on the pages. Each time that the mobile app requests data for a page, AOS creates a new session that uses the context of the user who is using the mobile app. AOS then uses the user’s context to open the corresponding forms (by using the corresponding menu items). AOS can open multiple forms in quick succession and perform actions on those forms (for example, filtering, opening FactBoxes, changing tab pages, and clicking buttons). Any business logic on the forms is also run as usual. Through that process, AOS collects the data values from the requested fields and then sends that data back to the mobile app.

The mobile app platform doesn’t assume connectivity to Finance and Operations apps. Activities such as navigation, data view, and data entry don’t require server connectivity after data has been cached.

Understanding navigation in the mobile app

Navigation in the mobile app consists of four simple concepts: the dashboard, workspaces, pages, and actions.
When you start the app, you land on the **dashboard**. On the **dashboard**, you can see a list of **workspaces** that are published in your environment.

In each **workspace**, you can see a list of **pages** that are available for that workspace.

On a **page**, you can view data that is collected from one or more forms.

From a **page**, you can navigate to other **pages** for related data, such as an entity details or lines.

On a **page**, you can see a list of **actions** that are available for that page.

**Actions** let you create or edit existing data.

**Notes**

At any time, you can pull-to-refresh in the mobile app to make the mobile app update its data or metadata. After you edit an existing workspace or publish a workspace, be sure to pull-to-refresh in the mobile app, in either the list of workspaces (if you added a workspace or business logic) or the list of pages (if you modified a page or an action). Workspaces that have been published are visible to all users. In Platform update 3, menu item security automatically hides pages that the user doesn’t have access to. If a user doesn’t have access to any pages in a workspace, the workspace itself is hidden.

**Using the mobile app designer**

The mobile app designer lets you select the specific data fields from forms that should appear in the mobile app.

A mobile workspace can be created through designer, using X++ attribute APIs or a combination of both. See [Configure workspaces by using the SysAppWorkspace class](#) for more details on using X++ APIs for building a mobile workspace.
1. Open the client.
2. Go to Settings > Mobile app.
3. Create a new workspace, or select an existing workspace to edit.
4. Specify the name of the workspace, an icon, and a color.
5. Add pages to the workspace, or edit an existing page.
6. Specify the name of the page.
7. Click Select Fields to select the data fields to add to the page.
8. Open the forms that have the data fields that you want to add, and then click the yellow plus sign (+) that appears next to the fields. The fields are added in the order that you select them in. You can add fields from multiple forms, in any order.
9. When you’ve finished selecting fields, click Done.
10. If you’ve added a field list to the page, you will see that the List type is specified for one of the items in the field list. You can optionally add a details page for items in that list by following these steps:
   a. Select the list by clicking on it in the designer.
   b. Click Add details page.
   c. Repeat steps 6 through 10 as you require.

**Refresh the app after you make changes**

### Additional resources
- Page design guidelines
- Action design guidelines
- Form design requirements
Mobile workspace business logic events provide places for developers to specify workspace configuration to enhance capability, and implement business-scenario-specific behaviors. All mobile business logic executes in the process of the mobile app, and business logic execution flow is controlled by the Operations mobile app framework.

Code that executes in business logic can make runtime modifications to the metadata of Pages, Actions, and Controls. These runtime modifications overlayer the static metadata that is cached in the app, but the modifications do not directly change the cached static metadata, nor do they affect the static metadata that is stored on the server. These runtime modifications only persist until the app is closed.

Code that executes in the business logic of the app can make runtime modifications to business data that is stored in the app. These modifications (when performed according to correct practices) participate in the normal data processing framework as other business data in the app. That means adhering to the offline-first capabilities and asynchronous save behaviors provided by the framework.
Before you begin to use the designer to build pages and actions, it's important that you plan the overall design of the mobile workspace that you want to build. We recommend that you orient your design around the entities that you plan to use in the mobile workspace. Don't begin by thinking about the forms that you want to use. From the perspective of the mobile app, the forms are just a mechanism for retrieving data, and the run-time UI behavior of a form isn't applicable to the mobile app. Therefore, you should first identify your entities and the relationships between them. For each entity, the following questions will help you decide how you should design your forms and pages.

**How do I create a list view for an entity in the mobile app?**

1. Identify or create a form in the web client that contains a grid for the entity.
2. Make sure that the grid is bound to the table that represents the entity.
3. Make sure that the form has a menu item that is root-navigable.
4. Make sure that the form can be opened directly via a URL that includes the menu item parameter.
5. Make sure that the filter pane enables the grid to be filtered based on the desired fields.
6. In the designer, create a page for the entity.
7. In the designer, put only a list on the page.
8. In the designer, put the desired fields in the list on the page.

**What if I don't want a list view for this entity?**

If you want just a details view for an entity, it's likely that the entity is a singleton for a given context (such as a given user or a given company). This pattern applies, for example, to a details view for an employee's own profile in a self-service workspace or a details view for the company context that is used for the current session. See the guidelines for creating a page for a details view.

**How do I create a details view for an entity in the mobile app?**

1. Identify or create a form in the web client that contains the details view for this entity.
2. Make sure that the Master Root Data Source on the form is bound to the table that represents the entity.
3. Make sure that the form has a menu item that is root-navigable.
4. Make sure that the form can be opened directly via a URL that includes the menu item parameter.
5. In the designer, create a page for the entity.
6. In the designer, put the desired fields on the page.

**How do I create list-to-details navigation for an entity in the mobile app?**

1. Make sure that you've created both a list view page and a details view page for the entity by using the designer.
2. Make sure that the entity for the list view is the same as the entity for the details view. In other words, the table that is bound to the grid on the form that is used for the list view must be the same table that is the Master Root Data Source on the form that is used for the details view.
3. Make sure that the form that is used for the details view can be filtered on a unique key field by using the filter pane.
4. In the designer, make sure that the list view page is linked to the details view page. Click the list, open the properties, and then set the details view page by using the lookup.
How do I add a reference field that enables navigation to a related entity?

1. Make sure that either a list view page or a details view page exists for the entity that contains the reference.

2. Make sure that the page contains the reference field from the entity that is being referenced.

3. Make sure that the referenced field is bound to the referenced entity’s data source, and that the referenced entity is *outer joined* (1-0..1) or *inner joined* (1-1) to the data source for the entity that contains the reference. For example, in the following illustration, FMRental is the entity that contains the reference, and FMVehicle is the referenced entity.

4. Make sure that you've created a separate details view page for the entity that is being referenced.

5. Make sure that the reference field has been added to the page.

6. In the designer, make sure that the reference field has been linked to the details view for the referenced entity. For example, in the following illustration, Vehicle-details is the details view page for the referenced entity.
How do I add a list that contains items from a related entity to a details view page?

1. Identify or create a form in the web client that contains the details view for the entity, and make sure that the form adheres to the guidelines in the “How do I create a details view for an entity in the mobile app” section.

2. Make sure that the form contains a grid that is bound to the table that represents the related entity.

3. Make sure that the table for the related entity is active joined to the table for the entity that contains the reference.

4. Create a details view page that contains the desired fields for the entity, and that also contains a list that has the desired fields from the related entity.

How do I make the list show up in-line in the details view?

1. Identify or create a form in the web client that contains the details view for the entity, and make sure that the form adheres to the guidelines in the “How do I create a details view for an entity in the mobile app” section.

2. Make sure that the form contains a grid that is bound to the table that represents the related entity.

3. Make sure that the table for the related entity is active joined to the table for the entity that contains the reference.

4. Use the form to create a details view page that contains the desired fields for the entity.

5. Use the same form to create a separate list view page that contains only a list that has the desired fields from the related entity.

6. On the details view page, add a PageLinkControl that links to the list view page. Currently, you must use business logic to add the PageLinkControl. The following example show the code that Fleet Management uses.
1. Identify or create a page that contains the controls with the data that you want.

2. Refer to the following code example, which hides the page from the navigation menus, and accesses data on the page using the provided APIs. Note that 'My-Hidden-Page' and 'My-Field-Id' are the names of the page and control, respectively, and can be found when viewing the corresponding page in the designer.

```javascript
function main(metadataService, dataService, cacheService, $q) {
    myField1Value = ''; // This variable will be populated in appInit, and can then be used elsewhere in the business logic.
    return {
        appInit: function (appMetadata) {
            var myHiddenPage = metadataService.findPage('My-Hidden-Page');
            if(myHiddenPage) {
                var dataPromise = dataService.getPageData(myHiddenPage.Id,'','',0);
                dataPromise.then(function (result) {
                    var myField1Id = metadataService.findControl(myHiddenPage, 'My-Field-1').Id;
                    myField1Value = result.data[myField1Id];
                });
            }
        }
    }
}
```

**How do I adjust the number of records returned in a list page using list fetch size?**

The number of records returned in a list page is controlled by the List fetch size value. The default is 50 records. The List fetch size indicates the maximum number of records returned by a page when it first loads, and the maximum number of records returned when search is used to find a specific set of records. Be careful not to make the value too large or it may negatively affect the user experience.

1. In the Mobile App designer, add a page containing a grid and select some fields from the grid.
2. Click the Grid node and then click Properties.
3. The Control properties dialog box will contain a default fetch size of 50 records.
4. Adjust the fetch size as needed.
Actions let users create, update, or delete data, and also run business processes on that data (such as submit, confirm, and post). A user who completes an action first supplies the data for the action (if the action accepts data input). When the user has finished supplying the data, the action is put into a queue of similar actions (which are sometimes referred to as data sync operations). If the device is connected/online, the queue is processed immediately. Otherwise, it’s processed the next time that the device is connected. The queue is processed asynchronously and doesn’t require the user’s attention unless there is an error during data synchronization. Errors of this type can occur because of server-side data validation. Actions are powered by a server-side mechanism that resembles Task recordings. This mechanism extracts the user’s input from the action and then automatically runs the business process steps on the server by using the input values that the user supplied. The mechanism automatically opens forms, clicks buttons on the forms, and enters the user’s input into controls on the forms. This process of playing back the action against the forms on the server occurs asynchronously, against “headless” forms. The mobile app informs the user when the process is completed, and shows the user any info, warning, or error messages that the forms logged. When you design an action, it’s important that you first consider what entity the action is related to. In the current framework, an action must operate on only one entity. An action should not update multiple entities at the same time. For example, an action to create a new sales order should create only the header for the order. It should not also try to create lines, because the lines are separate entities. When you decide to design the action, consider the following questions to determine how to proceed.

**How do I design an action that enables an entity to be created?**

1. Identify or create a list view page for the entity.
2. Make sure that the form that is used for the list view page includes a **New** button that can be used to add new records to the list.
3. Use the designer to create a new action for the page. While you’re designing the action, be careful not to perform any unnecessary actions. Enter data only in those fields that should be available to the user, and click only those buttons that are required (for example the **New** button and the **Save** button).

**How do I design an action that enables an entity to be edited?**

1. Identify or create a details view page for the entity.
2. Make sure that the form that is used for the details view page includes an **Edit** button that can be used to edit the visible record.
3. Make sure that the form that is used for the details view page lets users open a specific record by applying filters in the filter pane.
4. Use the designer to create a new action for the page. While you’re designing the action, be careful not to perform any unnecessary actions. Enter data only in those fields that should be available to the user, and click only those buttons that are required (for example, the **Edit** button and the **Save** button).

**How do I design an action that enables an entity to be deleted?**

1. Identify or create a details view page for the entity.
2. Make sure that the form that is used for the details view page includes a **Delete** button that can be used to delete the visible record.
3. Make sure that the form that is used for the details view page lets users open a specific record by applying filters in the filter pane.
4. Use the designer to create a new action for the page, and just click **Delete** as a part of the process of designing the action.
How do I design an action that enables a business action to be performed on an entity?

1. Identify or create a details view page for the entity.
2. Make sure that the form that is used for the details view page includes a **Delete** button that can be used to delete the visible record.
3. Make sure that the form that is used for the details view page lets users open a specific record by applying filters in the filter pane.
4. Use the designer to create a new action for the page, and just perform the steps that are required in the business action. You don’t necessarily have to enter data in fields as part of the action. For an action such as *submit*, you just have to click the **Submit** button (and acknowledge any confirmations that appear).

How do I design an action that enables a field value to be set via a rich lookup?

Lookups for fields in the mobile app don’t have a correlation to the advanced lookup behaviors in the cloud version of the app. Regardless of whether you have a custom lookup in the cloud version of the app or an automatic lookup that uses a simple query, the mobile app doesn’t run existing lookup code when it must determine which UI to show the user. (Remember that the user might be offline while using the app, and server-side code isn’t run until the action is synchronized.) However, lookup/control overrides such as *modified* are run when the value is set by the mobile back end as it synchronizes the data from the action. When the mobile app detects that a field on an action was selected from a lookup field on a form, it shows a device-native combo box/list picker control, and populates the items by directly querying the backing table of that lookup field. The items in the list show the user data from the TitleField for records in that table. Follow these steps to add the rich lookup experience to your action. This lookup experience includes a full-page multi-column lookup selector that has offline search.

1. Identify or create a list view page for the entity behind the lookup. You can reuse existing list view pages that you’ve already created.
2. After you’ve finished designing the action, select the field to add rich lookup functionality to, and then click **Properties**.
3. In the **Control properties** dialog box, select the list view page that you identified or created in step 1, and set the other related properties.
Manage mobile app

Customer

Done
4. Save and publish your changes to the action.

If you don’t see the property for the existing list view page or can’t access the Control properties dialog box when you’re designing your action, you might be using an older build of the app. In this case, you can still add rich lookup functionality by using a business logic file.

```
function main(metadataService, dataService, cacheService, $q) {
    return {
        appInit: function (appMetadata) {
            metadataService.configureLookup(
                // specify the name of the Action to add the lookup to
                'Add-Reservation',
                // specify the name of the Action's field to add the lookup to
                'FMRental_Customer',
                {
                    // specify the name of the Page for the Entity for the lookup
                    lookupPage: 'All-Customers',
                    // specify the Page's field which contains the value to set on the lookup
                    // this value should be the same value you can type into the field on the Form
                    valueField: 'FMCustomer_RecId',
                    // specify the Page's field which contains the value to display to the user
                    // this value is only used for display. The value field is passed to the Form
                    displayField: 'FMCustomer_FullName',
                    // set this to true to enable the rich lookup
                    showLookupPage: true
                }
            );
        },
    );
}
```

How do I prevent an action from appearing in the list of actions for a page?

To prevent an action from appearing in the list of actions for any page, call the following code from the `appInit()` section of your business logic. In this code, `action-name` is the name of your action (as specified in the Action name field in the designer).

```
function main(metadataService, dataService, cacheService, $q) {
    return {
        appInit: function (appMetadata) {
            metadataService.configureLookup('action-name', { visible: false });
        },
    );
}
```
This section provides valuable guidelines for building forms that work well with the mobile app.

- Each form must have an associated Display Menu Item.
  - The Display Menu Item's **Allow Root Navigation** property must be set to **Yes**. This setting enables the mobile framework to open the form that is referenced by the menu item.
- Each form must be directly accessible via its Display Menu Item.
  - To verify accessibility, open the menu item via a URL. Just append `&mi=` to the URL, where the value is the Application Object Tree (AOT) name of your menu item.
  - If the form doesn't open or show data when you access it in this way, the form won't work with the mobile app.
- Each form that shows data must have one Master Root Data Source.
  - This data source must be the first data source on the form (top-most in the designer).
  - This data source must not be joined to any other data sources.
- Each form must work with the data source filters.
  - After you open the form in the web client, open the filter pane by using the **Show filters** button.

Then click **Add a filter field**, and verify that the Master Root Data Source appears as the table for fields in the list of available fields. Other tables can also appear, but the Master Root Data Source **must** appear in this list. Otherwise, the mobile app won’t enable searches and navigation that uses context.

- Searching: The mobile app does online searches against data by using the Filters framework behind the scenes.
- Navigation that uses context: The mobile app enables list-to-details navigation (and other context-aware navigation) by first opening the target form via the menu item and then using the Filters framework to show only the specified record context.
- List-to-details navigation: The table that the grid is bound to on form A (the list form) must be the Master Root Data Source on the details form (form B). When a user selects a record in the list on form A, the mobile framework navigates with record context by applying filters on form B that uniquely identify the record.

**Design considerations**

**Using data methods**

You can use display methods to show data on pages (both list type pages and detail type pages). However, there
are two key points to remember when you use display methods:

- **Searching** – When a user performs an "online" search (that is, a search that is run against data in the web client instead of locally cached data), the search won’t match against display methods, because the Filtering framework in the web client doesn’t support searches against data methods. However, when a user does a search against locally cached data, the search will match against display methods, provided that the records have been cached on the device.

- **Offline** – If a user creates or updates data while their device isn’t connected to the server, temporary records are created in the local cache. Because these temporary records haven’t yet been processed in the web client, if the records have any fields that are automatically populated or defaults by server-side business logic, these fields will remain empty until the records have been synced with the web client. Display methods fall into this category of fields that will be empty for a temporary record.

**Designing for offline**

Unlike the web client, which is highly connected to the server and maintains an open user session that has open forms on the server, the mobile app creates user sessions (and opens forms) only in short bursts while the app is being synced with the server (via data read for pages, or via data write/update for actions). If there are no actions to sync with the server, and if the local data cache is up to date, the mobile app won’t communicate with the server as a user navigates around the app (unless the user triggers an explicit pull-to-refresh). It’s important that you keep this data flow pattern in mind while you design pages and actions in the mobile app. You should not expect form logic to run every time that a page is loaded or an action is started. You should also never expect form logic to run while a user is completing an action. Form logic is run only when the action is being synced with the server. The following list describes the only times when you should expect Form logic to run.

**Form logic runs right before a page is opened on the mobile app for the first time.**

1. When a user first opens a page, the mobile app reaches out to the web client and opens the associated forms. *During this process, logic such as form init and data source init is all run in the usual manner.*
2. The mobile app framework reads the required data directly from the controls on the forms and sends the data back to the mobile app.
3. The mobile app caches the data and shows it in the page on the mobile app.
4. Future attempts to open the page will load the cached data. *These attempts won’t run the form logic again, unless the user explicitly refreshes the page or the cache expires. (Currently, the cache set to expire after 30 minutes.)*

**Processing an action that has been submitted to the server from the mobile app**

1. When a user opens an action and fills in the data in that action, *no form logic is run.* A user can complete an action either offline or online. The system behaves the same way in both cases.
2. After the user clicks **Done/Save** on the action, the mobile app queues a data synchronization operation. This operation will be synced with the server when the mobile app is connected to the Internet.
3. When an Internet connection is detected (which can happen immediately after the action is completed) the mobile app sends the data synchronization operation to the server for processing.
4. While the operation is processed on the server, the framework opens the associated forms and enters the data from the action by passing values into the form controls. *During this process, form logic is run in the usual manner (init, modified, clicked, and so on, are all run).* However, the mobile user might have moved to a different part of the app while this processing is occurring. *Any form logic that shows/hides controls will have no effect on the UI that is seen in the mobile app.* Therefore, to minimize synchronization times, it’s best not to include any UI logic on the form.

**Building mobile versions of existing forms**

If you decide to modify existing forms so that they work with the mobile framework, instead of building new mobile-specific forms, you might have to conditionally change the form’s behavior for mobile-specific scenarios. You can use the following static X++ application programming interfaces (APIs) in your X++ code to determine whether the code is being accessed during a session where a web client user is designing pages/actions or...
during a session that the mobile framework back end created to load pages/actions for a mobile user. **When a form is being used with the mobile designer**

SysTaskRecorderController::isDesigningApp()

**When a form is being used by the mobile framework back end to load pages and run actions**

SysTaskRecorderController::isExecutingApp()

**Form control support**

The form controls for the various base data types (strings, dates, and numbers) and grids are supported. However, a few common controls have limited support. **Reference groups** Fields from within Reference groups controls are compatible when you design pages. However, they aren't compatible when you design Actions. Although you might be able to select these fields without experiencing any issues, Reference groups have a fundamental incompatibility with the mobile framework. We recommend that you not use Reference groups. Instead, add a control directly to the form, and then bind the control directly to the surrogate foreign key (SFK) by using the property sheet.
Configure workspaces by using the SysAppWorkspace class

Workspace class, **SysAppWorkspace**, is the starting point to create, configure and publish workspaces on the server. The following categories of APIs are available for use in sysAppWorkspace:

- **Workspace attributes** - This is used to create pages, tasks, entities, lookups, relationships in order to build mobile workspaces.
  
  - Download the sample project for Fleet Management Mobile App. This is an .axpp file found at [Dynamics365-for-Operations-mobile-FleetManagementSamples](Dynamics365-for-Operations-mobile-FleetManagementSamples).
  
  - After downloading the file, open Visual Studio on your Operations development environment, select *Dynamics 365 > Import Project*, and browse for the downloaded project file. On the same dialog box, select *Overwrite* and select *Create a new solution*. After the import is complete, build the solution (or build the Fleet Management model).
  
  - To review the example, start by reviewing the FMReservationManagementWorkspace class to see all the pages and actions included in the workspace. Use Solution Explorer to find page and task classes, and all the assets included in each. Use the API reference for more details on each API.
  
  - A mobile workspace can be created through designer pane, using X++ attribute APIs or a combination of both. See the "Use the workspace class to publish workspaces from AOT resources" section below for more details about how to import mobile app metadata from designer to AOT. The sample project Fleet Management Mobile App is a complete mobile app built using X++ attribute APIs.

- **Workspace metadata classes** - This is used to inspect and apply server-side business logic to metadata for mobile workspaces.

For a complete list of server-side APIs, see [Server-side development (workspace X++ APIs)](Server-side-development-workspace-X--APIs).

Create a new workspace class

To use the **SysAppWorkspace** class for your workspace, you must create a new class for the workspace by extending the **SysAppWorkspace** class. You can then use the new class to modify workspace metadata. The new class also provides hooks for life cycle management of the mobile app.

Follow these steps to create a new workspace class for your workspace.

1. Create a new class for your workspace, and extend it from the **SysAppWorkspace** class.

   ![MyNewWorkspace class extending SysAppWorkspace](MyNewWorkspace.png)

2. Add the **SysAppWorkspaceAttribute** attribute to the new class, and provide the **AppID** value of your workspace. You can find the app ID for your app on the *Summary* page in the mobile app designer.
3. Optional: If your workspace is an Application Object Tree (AOT) resource, provide the AOT resource name as the second parameter for the `SysAppWorkspaceAttribute` constructor.

Use the workspace class to publish workspaces from AOT resources

Workspaces can reside in the database. They can also reside in the AOT as resources. To provide visibility into workspaces that are stored in AOT resources, you must create a workspace class and point it to the name of the AOT resource that contains the workspace. Workspaces that are stored as AOT resources can't be edited or deleted by using the mobile app designer. Those workspace can only be exported.

Follow these steps to publish a workspace that resides in an AOT resource.
1. When you're developing a workspace that is stored in the database, you must export it from the mobile app designer so that it can be stored as an AOT resource. The workspace is exported as an XML file.

2. Delete the workspace from the mobile app designer. You will load it from an AOT resource later.

3. Create a new AOT resource, and select the exported workspace for the resource.

4. Create a new class for your workspace. This class should extend `SysAppWorkspace`. Apply the `SysAppWorkspaceAttribute` attribute to the class, and provide the app ID and the AOT resource name that contains the resource.

5. Build the class, and reopen the mobile app designer.

   The workspace is now published. It appears in the designer, but can't be edited or deleted. Note that the workspace is loaded from metadata.
Update a workspace that has already been published

If your workspace is part of an AOT resource, you can't edit it by using the mobile app designer. In the following example, a workspace that is named **MyWorkspace** exists in the AOT, and it has a backing class that is named **WorkspaceInAOT**.

Follow these steps to edit the workspace.

1. Export the workspace by using the mobile app designer. The designer automatically creates new app IDs for workspaces that are stored in the AOT.

2. Import the newly exported workspace by using the mobile app designer.
   
   a. Optional: Change the name so that the newly added workspace can be distinguished from other workspaces.
   
   b. Copy the app ID of the newly created workspace.
3. Create a new class that extends your backing class, apply the `SysAppWorkspaceAttribute` attribute, and specify the new app ID.

You can now continue to work with your new workspace and the backing class. After you've finished making your changes, you can merge them with the AOT-based workspace.

### Delete a workspace that is an AOT resource

When a mobile workspace is stored as an AOT resource, you can’t delete it by using the mobile app designer. Follow these steps to delete a workspace that exists as an AOT resource.

1. Delete the AOT resource that contains the workspace.

2. Delete the workspace class that was created for the workspace.
3. Do a full model build that contains the AOT resource and the class. The following illustrations shows a full build of the Application Foundation model. The Application Foundation model also contains the AOT resource and workspace class. To speed up the full build, you can clear all the selections on the **Options** tab.

4. When the build is completed, reopen the mobile app designer, and verify that the workspace is no longer there.
The fields on a mobile app page can be customized so that they are shown as email addresses, phone numbers, or URLs.

**Email field**

You can mark a field as an email address field by using business logic. Then, when a user clicks the field, the default mobile email app starts, and the field value appears as the email address in the app.

**Phone field**

You can mark a field as a phone number field by using business logic. Then, when a user clicks the field, the mobile dialer app starts, and the field value appears as the phone number in the app.

**NOTE**

On iOS, if the phone number isn't valid, it might not trigger the mobile dialer app.

**URL field**

You can mark a field as a URL field by using business logic. Then, when a user clicks the field, the URL opens in the default mobile browser, and the field value appears in the address bar.

**NOTE**

On iOS, you must provide a complete URL (that is, a URL that starts with a protocol, such as https). Otherwise, the URL isn't opened in the browser. A URL such as www.microsoft.com doesn't work. Instead, the URL must be specified as https://www.microsoft.com.

**Example**

This example shows how to configure the customer email address and phone number fields so that they can clicked and opened in the appropriate iOS apps.

Before the fields are customized, they can't be clicked, as shown in the following image.
Follow these steps to specify that a field is a link.

1. Add the following lines to the `appInit` method. You call the `configureControl` method, and pass in the page name and control name. You then supply the `LinkType` value for the control. The following values are supported: `Telephone`, `Email`, and `Url`.

   ```javascript
   metadataService.configureControl('PageName', 'ControlName', { LinkType: 'Telephone' });
   metadataService.configureControl('PageName', 'ControlName', { LinkType: 'Email' });
   metadataService.configureControl('PageName', 'ControlName', { LinkType: 'Url' });
   ```

2. Upload the updated business logic file by using the mobile app designer.

3. Update the workspace metadata in the mobile client.

The fields now appear as links.

Phone

Actions
Although a pageLink control can be used to show counts (totals), it can be slow, because it must load the target page before it counts the number of rows. Additionally, the count that is calculated can be incorrect, because there is a limit on the number of rows that are retrieved.

If you want to make mobile workspaces work more quickly, we recommended that you use a regular field to show the count and then model the field as a pageLink control in the mobile client.

The following example uses the Fleet Management app. In the Fleet Management app, the workspace shows the total number of customers, reservations, and vehicles. Previously, these counts came from a pageLink control that had AllCustomers, AllReservations, and AllVehicles as targets. The pageLink control loaded the rows and did the count. (This approach isn't the recommended approach.)

Follow these steps to configure the workspace page to use the recommended approach.

1. On the server, create a new form to contain fields that are also on the server. (You can also add the new fields to an existing form). In the following illustration, a new FMMobSummary form is created that has three fields.
2. Create a page by using the mobile app designer for the FMMobSummary form.

3. Update the business logic to transform the fields into a pageLink control. Use the configureControl method to add a navigation target to the fields. The fields are then configured as pageLink controls. The arguments for the configureControl method are the page name, the control name, and an object of properties that must be updated.

4. Update the workspace design. Embed the summary page as a part in the workspace page. Reference the fields that are now configured as pageLink controls. Provide a style, and set the showCount:true property, so that the count is shown on the pageLink control.
By using this approach, you also get the localized labels for `pageLink` controls. The result is a much faster experience when workspaces are loaded.
This topic describes how to limit a user’s access to a workspace.

**Assign a menu item to workspace**

Workspaces can be tied to a menu item. Users who don’t have access to the menu item can’t use the workspace, because the workspace is shown only to users who have rights to the menu item.

If a menu item isn’t assigned to a workspace, the workspace is always shown to the user.

Follow these steps to help secure your workspaces by assigning a menu item.

1. Add a `SysAppWorkspaceSecurityAttribute` attribute to the workspace class, and specify the menu item to assign to the workspace.

   ```java
   [SysAppWorkspaceSecurityAttribute("4CB34728-4CB2-453D-AF9-08A680F2D77F"),
   SysAppWorkspaceSecurityAttribute("BatchGroup")]
   ```

2. Build the menu item and workspace. To test your changes, sign in to mobile app by using a user account that doesn’t have access to the menu item.

**Override the `workspaceHidden` method**

You can also specify whether the workspace is hidden or shown, based on parameters. By overriding the `workspaceHidden` method, you enable your code to control the visibility of the workspace, as shown in the following code example.

```csharp
/// <summary>
/// Used to control if a workspace is hidden or not
/// </summary>
/// <returns>Returns true if the workspace is hidden; otherwise false</returns>
public boolean workspaceHidden()
{
    boolean ret;
    ret = super();
    return ret;
}
```

**Add a menu item and override the `workspaceHidden` method**

You can use both the preceding methods in your app. The menu item provides a security check, and the `workspaceHidden` method contains additional logic that is related to the visibility of the workspace.
You can use workspace classes in several ways to provide localization support to workspaces.

**Use config objects to pass localized labels**

A config object can be added to the workspace metadata when it's requested by the mobile app. Later, the config object can be used to provide localization support.

For example, the following workspace requires localized labels for the `pageLink` control that you added via the business logic.

The business logic for the app contains a call to the `addLink` method, as shown in the following illustration. This `addLink` method adds a link to the `Rentals` page for the current customer. In this case, the label for the link is `Rentals`. However, because there isn't a localized label for the link, the link always appears as `Rentals`.

```javascript
```
To use a config object to provide localized labels, follow these steps.

1. Create a config class that contains the fields for the labels. One field, `rentalLinkLabel`, is added to the class that will contain the label for the `pageLink` control. The config class must be a data contract class.

```csharp
[DataContractAttribute("ReservationManagementLabels")]
class ReservationManagementWorkspaceLabels
{
    str rentalLinkLabel;
    [DataMemberAttribute("RentalLinkLabel")] public str rentalLinkLabel(str _rentalLinkLabel = rentalLinkLabel)
    {
        rentalLinkLabel = _rentalLinkLabel;
        return rentalLinkLabel;
    }
}
```

2. The config class is used by a workspace class for the workspace. The workspace class requires the `appId` value of the workspace. You can find the app ID in the App designer, as shown in the following illustration.

The following illustration shows what the workspace class looks like when the `appId` value is set on the attribute. The class also contains a method, `addConfig`, that sets a config object that contains the value for the label.
Use a workspace class to update the workspace title and description

A workspace class can be used to provide localized strings for the workspace title and description. If you don’t localize the title and description, the fields will be in the language that you implemented them in. In this example, we will localize a workspace where **MyWorkspace** is the title and **A sample workspace** is the description.
1. If you don't have a workspace class for your workspace, create a workspace class.

2. Override the `getWorkspaceMetadata` method to get the workspace metadata. You must have the workspace metadata to provide labels for the workspace title and description fields.

3. Use the `workspaceTitle` and `workspaceDescription` properties to set the workspace title and description from a label. In the following illustration, placeholders are assigned to the `workspaceTitle` and `workspaceDescription` properties.

```java
class WorkspaceInAOT extends SysAppWorkspace
{
    public SysAppWorkspaceMetadata getWorkspaceMetadata()
    {
        SysAppWorkspaceMetadata workspaceMetadata;
        workspaceMetadata = super();
        this.updateWorkspaceTitleAndDescription(workspaceMetadata);
        return workspaceMetadata;
    }

    private void updateWorkspaceTitleAndDescription(SysAppWorkspaceMetadata _workspaceMetadata)
    {
        _workspaceMetadata.workspaceTitle("@Client:Workspace");
        _workspaceMetadata.workspaceDescription("@ApplicationFoundation:FieldDescriptionsCaption");
    }
}
```

4. Build the workspace class.

5. Update the app list on the mobile client.

The following illustration shows the title and description on a phone that uses English and Danish.
Arbejdsområde
Beskrivelse af feltet
When you use the mobile app designer to select fields for actions, some properties can be inferred. These properties include the field length, the type, and whether the field is mandatory. The workspace classes can be used to update these properties. For example, you might want to specify that the Name field is mandatory when a customer record is created, as shown in the following images.
Follow these steps to make the Delivery terms field mandatory by using the workspace class.

1. Get the control name by using the app designer. In this example, the control name is DynamicDetail_DlvTerm.

2. Add the following code to set the Mandatory property for the control. This code uses the reflection-based setProperty method to set the Mandatory property.

   ```java
   public SysAppWorkspaceMetadata getWorkspaceMetadata()
   {
     SysAppWorkspaceMetadata appMetadata;
     appMetadata = super();
     var createCustAction = appMetadata.getAction("createCust");
     this.setCustAccountMandatory(createCustAction);
     return appMetadata;
   }
   private void setCustAccountMandatory(SysAppActionMetadata _createCustAction)
   {
     var custAccount = +createCustAction.getControl("DynamicDetail_DlvTerm");
     custAccount.setProperty("Mandatory", true);
   }
   ```

3. Build the solution, and then update the app metadata on the mobile app.

The Delivery terms field is now marked as Mandatory, as shown in the following illustration.
Name

Delivery terms

Mode of delivery
Class SysAppActionAttribute

SysAppActionAttribute used for decorating methods defining actions of workspace

### Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppActionAttribute class</td>
</tr>
<tr>
<td>pageMethodName</td>
<td>str</td>
<td>Gets the get method name that forms the page under which this task resides</td>
</tr>
<tr>
<td>actionTitle</td>
<td>str</td>
<td>Gets the Action Title</td>
</tr>
<tr>
<td>actionDescription</td>
<td>str</td>
<td>Gets the Action Description</td>
</tr>
<tr>
<td>crudOperationType</td>
<td>SysAppCRUDOperation</td>
<td>Gets the Crud Operation Type like Create, Update, Delete</td>
</tr>
</tbody>
</table>

### Method new

Creates a new instance of SysAppActionAttribute class

```java
public void new ([str _actionTitle], [str _actionDescription], [SysAppCRUDOperation _crudOperationType], [str _pageMethodName])
```

#### Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_actionTitle</td>
<td>str</td>
<td>True</td>
<td>Action title</td>
</tr>
<tr>
<td>_actionDescription</td>
<td>str</td>
<td>True</td>
<td>Action description</td>
</tr>
<tr>
<td>_crudOperationType</td>
<td>SysAppCRUDOperation</td>
<td>True</td>
<td>CRUD operation like Create, Update, Delete</td>
</tr>
<tr>
<td>_pageMethodName</td>
<td>str</td>
<td>True</td>
<td>Name of the method constructing parent page</td>
</tr>
</tbody>
</table>

### Method pageMethodName

Gets the get method name that forms the page under which this task resides

```java
public str pageMethodName ()
```

### Return Value

...
The page method name that forms the page under which this task resides

**Method actionTitle**
Gets the Action Title

```java
public str actionTitle ()
```

**Return Value**
The action title

**Method actionDescription**
Gets the Action Description

```java
public str actionDescription ()
```

**Return Value**
The page description

**Method crudOperationType**
Gets the Crud Operation Type like Create, Update, Delete

```java
public SysAppCRUDOperation crudOperationType ()
```

**Return Value**
The Crud Operation Type like Create, Update, Delete

**Class SysAppActionMetadata**
This class can be used to access and update AX mobile workspace action metadata

**Methods**

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td></td>
</tr>
<tr>
<td>getName</td>
<td>str</td>
<td>Returns the action name</td>
</tr>
<tr>
<td>actionTitle</td>
<td>str</td>
<td>Gets or sets the action title</td>
</tr>
<tr>
<td>actionDescription</td>
<td>str</td>
<td>Gets or sets the action description</td>
</tr>
<tr>
<td>actionHidden</td>
<td>boolean</td>
<td>Gets or sets whether action is hidden</td>
</tr>
<tr>
<td>actionOrder</td>
<td>int</td>
<td>Gets or sets the action order</td>
</tr>
<tr>
<td>getControl</td>
<td>SysAppControlMetadata</td>
<td>Returns the control on the current action having the provided control name</td>
</tr>
<tr>
<td>getControlEnumerator</td>
<td>MapEnumerator</td>
<td>Returns a map enumerator that can be used to enumerate action controls. Where Key is control name and value is of type SysAppControlMetadata</td>
</tr>
</tbody>
</table>
### Method `new`

```java
```

#### Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
</table>

### Method `getActionName`

Returns the action name

```java
public str getActionName ()
```

#### Return Value

The action name

### Method `actionTitle`

Gets or sets the action title

```java
public str actionTitle ([str _actionTitle])
```

#### Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_actionTitle</td>
<td>str</td>
<td>True</td>
<td>The action title</td>
</tr>
</tbody>
</table>

#### Return Value

The action title

### Method `actionDescription`

Gets or sets the action description

```java
public str actionDescription ([str _actionDescription])
```

#### Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_actionDescription</td>
<td>str</td>
<td>True</td>
<td>The action description</td>
</tr>
</tbody>
</table>

#### Return Value

The action description

### Method `actionHidden`

Gets or sets whether action is hidden

```java
public boolean actionHidden ([boolean _actionHidden])
```
<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_actionHidden</td>
<td>boolean</td>
<td>True</td>
<td>Action hidden value</td>
</tr>
</tbody>
</table>

**Return Value**
True if the action is hidden; otherwise false

**Method actionOrder**
Gets or sets the action order

```java
public int actionOrder ([int _actionOrder])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_actionOrder</td>
<td>int</td>
<td>True</td>
<td>The action order</td>
</tr>
</tbody>
</table>

**Return Value**
The action order

**Method getControl**
Returns the control on the current action having the provided control name

```java
public SysAppControlMetadata getControl (str _controlName)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_controlName</td>
<td>str</td>
<td>False</td>
<td>The control name that will be used to search for control</td>
</tr>
</tbody>
</table>

**Return Value**
An object of SysAppControlMetadata is returned if a control with the provided control name exist on the action; otherwise null

**Method getControlEnumerator**
Returns a map enumerator that can be used to enumerate action controls. Where Key is control name and value is of type SysAppControlMetadata

```java
public MapEnumerator getControlEnumerator ()
```

**Return Value**
A map enumerator

**Class SysAppAttributeHelper**
SysAppAttributeHelper class for fetching attributes from all the extended class

**Methods**
### Method getNameFromEntity

`getNameFromEntity` method retrieves a name from an entity.

- **Returns**: SysAttribute
- **Description**: gets attribute from class

#### Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_sysClass</td>
<td>SysDictClass</td>
<td>False</td>
<td>class for which attributes is required</td>
</tr>
<tr>
<td>_attributeType</td>
<td>SysAppAttributeType</td>
<td>False</td>
<td>Type of attribute like SysAppEntityAttribute</td>
</tr>
</tbody>
</table>

### Class SysAppCollectionAttribute

SysAppCollectionAttribute is used for decorating methods forming list control.

### Methods

- **Method new**
  - **Returns**: void
  - **Description**: Constructor

#### Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_itemContractName</td>
<td>str</td>
<td>False</td>
<td>Data contract name of list item</td>
</tr>
<tr>
<td>_label</td>
<td>str</td>
<td>True</td>
<td>List control label</td>
</tr>
<tr>
<td>_relationshipName</td>
<td>str</td>
<td>True</td>
<td>Relationship name. By default the entity name of the list item is used as relationship name</td>
</tr>
</tbody>
</table>

### Class SysAppControlMetadata

Represents an X++ wrapper over the managed ControlMetadata object to facilitate, passing around the object as X++ object.

### Methods
<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of the control metadata</td>
</tr>
<tr>
<td>getBaseLanguageId</td>
<td>str</td>
<td>Returns the base language ID for the app</td>
</tr>
<tr>
<td>getControlName</td>
<td>str</td>
<td>Returns the control name</td>
</tr>
<tr>
<td>controlLabel</td>
<td>str</td>
<td>Gets and sets the control label</td>
</tr>
<tr>
<td>controlHidden</td>
<td>boolean</td>
<td>Gets and sets whether the control is hidden</td>
</tr>
<tr>
<td>controlOrder</td>
<td>int</td>
<td>Gets or sets the control order</td>
</tr>
<tr>
<td>controlMandatory</td>
<td>boolean</td>
<td>Gets or sets the control mandatory</td>
</tr>
<tr>
<td>controlAllowNegative</td>
<td>boolean</td>
<td>Gets or sets the control allow negative</td>
</tr>
<tr>
<td>controlMaxLength</td>
<td>int</td>
<td>Gets or sets the control max length</td>
</tr>
<tr>
<td>getProperty</td>
<td>anytype</td>
<td>Gets the control property referenced by the key</td>
</tr>
<tr>
<td>setProperty</td>
<td>void</td>
<td>Sets the control property referenced by the key</td>
</tr>
</tbody>
</table>

**Method new**

Creates a new instance of the control metadata

```java
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_baseLanguageId</td>
<td>str</td>
<td>True</td>
<td>The base language</td>
</tr>
</tbody>
</table>

**Method getBaseLanguageId**

Returns the base language ID for the app

```java
public str getBaseLanguageId ()
```

**Return Value**

The base language ID

**Method getControlName**
Returns the control name

```
public str getControlName ()
```

**Return Value**
The control name

**Method controlLabel**
Gets and sets the control label

```
public str controlLabel ([str _controlLabel])
```

**Parameters**
<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_controlLabel</td>
<td>str</td>
<td>True</td>
<td>The control label</td>
</tr>
</tbody>
</table>

**Return Value**
The control label

**Method controlHidden**
Gets and sets whether the control is hidden

```
public boolean controlHidden ([boolean _controlHidden])
```

**Parameters**
<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_controlHidden</td>
<td>boolean</td>
<td>True</td>
<td>Control hidden value</td>
</tr>
</tbody>
</table>

**Return Value**
True if the control is hidden; otherwise false

**Method controlOrder**
Gets or sets the control order

```
public int controlOrder ([int _controlOrder])
```

**Parameters**
<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_controlOrder</td>
<td>int</td>
<td>True</td>
<td>The control order</td>
</tr>
</tbody>
</table>

**Return Value**
The control order

**Method controlMandatory**
Gets or sets the control mandatory

```
public boolean controlMandatory ([boolean _controlMandatory])
```
Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_controlMandatory</td>
<td>boolean</td>
<td>True</td>
<td>The control mandatory</td>
</tr>
</tbody>
</table>

Return Value

The control mandatory

Method controlAllowNegative

Gets or sets the control allow negative

```java
public boolean controlAllowNegative ([boolean _controlAllowNegative])
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_controlAllowNegative</td>
<td>boolean</td>
<td>True</td>
<td>The control allows negative</td>
</tr>
</tbody>
</table>

Return Value

The control allows negative

Method controlMaxLength

Gets or sets the control max length

```java
public int controlMaxLength ([int _controlMaxLength])
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_controlMaxLength</td>
<td>int</td>
<td>True</td>
<td>The control max length</td>
</tr>
</tbody>
</table>

Return Value

The control max length

Method getProperty

Gets the control property referenced by the key

```java
public anytype getProperty (str _key)
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_key</td>
<td>str</td>
<td>False</td>
<td>The name of the control property</td>
</tr>
</tbody>
</table>

Return Value

The property value

Method setProperty

Sets the control property referenced by the key
```java
public void setProperty (str _key, anytype _value)
```

### Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_key</td>
<td>str</td>
<td>False</td>
<td>The name of the control property</td>
</tr>
<tr>
<td>_value</td>
<td>anytype</td>
<td>False</td>
<td>The value of the control property</td>
</tr>
</tbody>
</table>

## Class SysAppEntityAttribute

SysAppEntityAttribute used for decorating data contract entities

### Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Constructor</td>
</tr>
<tr>
<td>name</td>
<td>str</td>
<td>Gets the name of the entity</td>
</tr>
<tr>
<td>entityKey</td>
<td>str</td>
<td>Gets the entity key</td>
</tr>
</tbody>
</table>

### Method new

Constructor

```java
public void new (str _name, str _entityKey)
```

#### Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_name</td>
<td>str</td>
<td>False</td>
<td>Entity name</td>
</tr>
<tr>
<td>_entityKey</td>
<td>str</td>
<td>False</td>
<td>Name of the entity's key</td>
</tr>
</tbody>
</table>

### Method name

Gets the name of the entity

```java
public str name ()
```

#### Return Value

Name of the entity

### Method entityKey

Gets the entity key

```java
public str entityKey ()
```
Class SysAppEntityContext
SysAppEntityContext used for defining entity context

Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>constructFromParams</td>
<td>SysAppEntityContext</td>
<td>Constructs SysAppEntityContext from entityName and entityId</td>
</tr>
<tr>
<td>constructFromBuffer</td>
<td>SysAppEntityContext</td>
<td>Constructs SysAppEntityContext from table buffer</td>
</tr>
<tr>
<td>entityName</td>
<td>str</td>
<td>Entity name on which filter applies</td>
</tr>
<tr>
<td>entityId</td>
<td>str</td>
<td>Field value on which filter applies</td>
</tr>
</tbody>
</table>

Method constructFromParams
Constructs SysAppEntityContext from entityName and entityId

```java
public SysAppEntityContext constructFromParams (str _entityName, str _entityId)
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_entityName</td>
<td>str</td>
<td>False</td>
<td>Entity name</td>
</tr>
<tr>
<td>_entityId</td>
<td>str</td>
<td>False</td>
<td>Entity value</td>
</tr>
</tbody>
</table>

Return Value
Instance of SysAppEntityContext

Method constructFromBuffer
Constructs SysAppEntityContext from table buffer

```java
public SysAppEntityContext constructFromBuffer (Common _tableBuffer)
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_tableBuffer</td>
<td>Common</td>
<td>False</td>
<td>table buffer forming the entity</td>
</tr>
</tbody>
</table>

Return Value
Instance of SysAppEntityContext

Method entityName
Entity name on which filter applies
public str entityName ([str _entityName])

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_entityName</td>
<td>str</td>
<td>True</td>
<td>Entity name</td>
</tr>
</tbody>
</table>

Return Value

Entity name

Method entityId

Field value on which filter applies

public str entityId ([str _entityId])

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_entityId</td>
<td>str</td>
<td>True</td>
<td>Entity value</td>
</tr>
</tbody>
</table>

Return Value

Entity value

Class SysAppFieldAttribute

SysAppFieldAttribute used for decorating methods forming bound fields

Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppFieldAttribute class</td>
</tr>
</tbody>
</table>

Method new

Creates a new instance of SysAppFieldAttribute class

public void new (str _fieldName, str _label)

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_fieldName</td>
<td>str</td>
<td>False</td>
<td>Entity field name with which control is bound</td>
</tr>
<tr>
<td>_label</td>
<td>str</td>
<td>False</td>
<td>Control label</td>
</tr>
</tbody>
</table>

Class SysAppFieldMultiSelectHelper

A helper class to provide helper methods for multi select scenarios used with D365 mobile app
Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppFieldMultiSelectHelper class</td>
</tr>
<tr>
<td>getSelectedRecIds</td>
<td>container</td>
<td>Returns a container of recIds of the records that were selected</td>
</tr>
<tr>
<td>getSelectedValues</td>
<td>container</td>
<td>Returns a container of selected values</td>
</tr>
<tr>
<td>getSelectedRecords</td>
<td>Common</td>
<td>Returns a buffer that contains all the selected records. The buffer is marked as temp. Later a while-Select can be used to iterate through all the records</td>
</tr>
<tr>
<td>setControlValue</td>
<td>void</td>
<td>A setter to set the multiselect control value</td>
</tr>
</tbody>
</table>

**Method new**

Creates a new instance of SysAppFieldMultiSelectHelper class

```java
public void new (TableId _multiSelectTableId, FieldId _valueFieldId, FormStringControl _multiSelectControl)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_multiSelectTableId</td>
<td>TableId</td>
<td>False</td>
<td>The backing tableId for the field</td>
</tr>
<tr>
<td>_valueFieldId</td>
<td>FieldId</td>
<td>False</td>
<td>The fieldId for the field that will be shown in the multi select control</td>
</tr>
<tr>
<td>_multiSelectControl</td>
<td>FormStringControl</td>
<td>False</td>
<td>The string control that will be the multi select control</td>
</tr>
</tbody>
</table>

**Method getSelectedRecIds**

Returns a container of recIds of the records that were selected

```java
public container getSelectedRecIds ()
```

**Return Value**

A container of recOds for the records that were selected

**Method getSelectedValues**

Returns a container of selected values

```java
public container getSelectedValues ()
```

**Return Value**

A container of selected values
**Method getSelectedRecords**

Returns a buffer that contains all the selected records. The buffer is marked as temp. Later a while-Select can be used to iterate through all the records.

```java
public Common getSelectedRecords ()
```

**Return Value**

A buffer containing all the selected records.

**Method setControlValue**

A setter to set the multi select control value.

```java
public void setControlValue (str _value)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_value</td>
<td>str</td>
<td>False</td>
<td>A colon separated value that will be used by SysAppFieldMultiSelectHelper</td>
</tr>
</tbody>
</table>

**Class SysAppFilterContext**

SysAppFilterContext class that holds context values.

**Methods**

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityName</td>
<td>str</td>
<td>Entity name on which filter applies</td>
</tr>
<tr>
<td>filterFieldName</td>
<td>str</td>
<td>Field name on which filter applies</td>
</tr>
<tr>
<td>filterFieldValueList</td>
<td>List</td>
<td>Gets the list of filter field values based on which filter happens</td>
</tr>
<tr>
<td>operator</td>
<td>str</td>
<td>Operator based on which result will be fetched</td>
</tr>
<tr>
<td>addFilterFieldValue</td>
<td>void</td>
<td>Adds filter field value</td>
</tr>
</tbody>
</table>

**Method entityName**

Entity name on which filter applies

```java
public str entityName ([str _entityName])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_entityName</td>
<td>str</td>
<td>True</td>
<td>Entity name on which filter applies</td>
</tr>
</tbody>
</table>

**Return Value**  
Entity name on which filter applies

**Method filterFieldName**  
Field name on which filter applies

```java
public str filterFieldName ([str _filterFieldName])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_filterFieldName</td>
<td>str</td>
<td>True</td>
<td>Field name on which filter applies</td>
</tr>
</tbody>
</table>

**Return Value**  
Field name on which filter applies

**Method filterFieldValueList**  
Gets the list of filter field values based on which filter happens

```java
public List filterFieldValueList ()
```

**Return Value**  
List of filter field values based on which filter happens

**Method operator**  
Operator based on which result will be fetched

```java
public str operator ([str _operator])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_operator</td>
<td>str</td>
<td>True</td>
<td>Operator based on which result will be fetched</td>
</tr>
</tbody>
</table>

**Return Value**  
Operator based on which result will be fetched

**Method addFilterFieldValue**  
Adds filter field value

```java
public void addFilterFieldValue ( _filterFieldValuelist)
```

**Parameters**
## Class SysAppLookUpAttribute

SysAppPageAttribute used for decorating pages that are also lookup pages

### Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppLookUpAttribute class</td>
</tr>
<tr>
<td>displayFieldName</td>
<td>str</td>
<td>Gets the display field name of lookup control</td>
</tr>
<tr>
<td>valueFieldName</td>
<td>str</td>
<td>Gets the value field name of lookup control</td>
</tr>
</tbody>
</table>

### Method new

Creates a new instance of SysAppLookUpAttribute class

```java
public void new (str _displayFieldName, str _valueFieldName)
```

### Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_displayFieldName</td>
<td>str</td>
<td>False</td>
<td>Lookup display field. Name of any control of lookup page</td>
</tr>
<tr>
<td>_valueFieldName</td>
<td>str</td>
<td>False</td>
<td>Lookup value field. Name of control formed by root data contract constructing lookup page</td>
</tr>
</tbody>
</table>

### Method displayFieldName

Gets the display field name of lookup control

```java
public str displayFieldName ()
```

### Return Value

The display field name of lookup control

### Method valueFieldName

Gets the value field name of lookup control

```java
public str valueFieldName ()
```

### Return Value

The value field name of lookup control
The value field name of lookup control

Class SysAppLookupFieldAttribute
SysAppLookupFieldAttribute used for decorating look up fields of action

Methods

<table>
<thead>
<tr>
<th>METHOD_NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppLookupFieldAttribute class</td>
</tr>
<tr>
<td>entityName</td>
<td>str</td>
<td>Gets the name of the entity with which lookup page is related</td>
</tr>
</tbody>
</table>

Method new
Creates a new instance of SysAppLookupFieldAttribute class

```java
public void new (_name)
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_name</td>
<td>False</td>
<td>Name of the entity with which lookup page is related</td>
<td></td>
</tr>
</tbody>
</table>

Method entityName
Gets the name of the entity with which lookup page is related

```java
public str entityName ()
```

Return Value
Name of the entity

Class SysAppPageAttribute
SysAppPageAttribute used for decorating methods defining page of workspace

Methods

<table>
<thead>
<tr>
<th>METHOD_NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppPageAttribute class</td>
</tr>
<tr>
<td>pageTitle</td>
<td>str</td>
<td>Gets the Page Title of the page</td>
</tr>
<tr>
<td>pageDescription</td>
<td>str</td>
<td>Gets the Page Description</td>
</tr>
</tbody>
</table>

Method new
Creates a new instance of SysAppPageAttribute class
public void new ([str _pageTitle], [str _pageDescription])

### Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_pageTitle</td>
<td>str</td>
<td>True</td>
<td>The page title</td>
</tr>
<tr>
<td>_pageDescription</td>
<td>str</td>
<td>True</td>
<td>The page description</td>
</tr>
</tbody>
</table>

### Method pageTitle

Gets the Page Title of the page

```java
public str pageTitle ()
```

**Return Value**

The page title

### Method pageDescription

Gets the Page Description

```java
public str pageDescription ()
```

**Return Value**

The page description

### Class SysAppPageMetadata

This class can be used to access and update AX mobile workspace page metadata

### Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td></td>
</tr>
<tr>
<td>getPageName</td>
<td>str</td>
<td></td>
</tr>
<tr>
<td>pageTitle</td>
<td>str</td>
<td>Gets and sets the page title</td>
</tr>
<tr>
<td>pageDescription</td>
<td>str</td>
<td>Gets or sets the page description</td>
</tr>
<tr>
<td>pageHidden</td>
<td>boolean</td>
<td>Gets and sets whether the page is hidden in the workspace</td>
</tr>
<tr>
<td>pageOrder</td>
<td>int</td>
<td>Gets or sets the page order</td>
</tr>
<tr>
<td>getControl</td>
<td>SysAppControlMetadata</td>
<td>Returns the control on the current page having the provided control name</td>
</tr>
</tbody>
</table>
### Method new

```java
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
</table>

### Method getPageName

Returns the page name

```java
public str getPageName ()
```

**Return Value**

The page name

### Method pageTitle

Gets and sets the page title

```java
public str pageTitle ([str _pageTitle])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_pageTitle</td>
<td>str</td>
<td>True</td>
<td>The page title</td>
</tr>
</tbody>
</table>

**Return Value**

The page title

### Method pageDescription

Gets or sets the page description

```java
public str pageDescription ([str _pageDescription])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_pageDescription</td>
<td>str</td>
<td>True</td>
<td>The page description</td>
</tr>
</tbody>
</table>

**Return Value**

The page description
**Method pageHidden**

Gets and sets whether the page is hidden in the workspace

```java
public boolean pageHidden (boolean _pageHidden)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_pageHidden</td>
<td>boolean</td>
<td>True</td>
<td>page hidden value</td>
</tr>
</tbody>
</table>

**Return Value**

True if the current page is hidden in workspace; otherwise false

**Method pageOrder**

Gets or sets the page order

```java
public int pageOrder (int _pageOrder)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_pageOrder</td>
<td>int</td>
<td>True</td>
<td>The page order</td>
</tr>
</tbody>
</table>

**Return Value**

The page order

**Method getControl**

Returns the control on the current page having the provided control name

```java
public SysAppControlMetadata getControl (str _controlName)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_controlName</td>
<td>str</td>
<td>False</td>
<td>The control name that will be used to search for control</td>
</tr>
</tbody>
</table>

**Return Value**

An object of SysAppControlMetadata is returned if a control with the provided control name exist on the page; otherwise null

**Method getControlEnumerator**

Returns a map enumerator that can be used to enumerate page controls. Where Key is control name and value is of type SysAppControlMetadata

```java
public MapEnumerator getControlEnumerator ()
```

**Return Value**

A map enumerator
Class SysAppProjectionAttribute

SysAppProjectionAttribute used for decorating methods forming unbound fields

Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppControlMetadataAttributes class</td>
</tr>
</tbody>
</table>

Method new

Creates a new instance of SysAppControlMetadataAttributes class

```java
public void new (str _label)
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_label</td>
<td>str</td>
<td>False</td>
<td>Control label</td>
</tr>
</tbody>
</table>

Class SysAppRelationalAttribute

SysAppRelationalAttribute used for decorating reference controls

Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Constructor</td>
</tr>
</tbody>
</table>

Method new

Constructor

```java
public void new ([str _name])
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_name</td>
<td>str</td>
<td>True</td>
<td>Property name of the referenced entity</td>
</tr>
</tbody>
</table>

Class SysAppRequestParams

Request class for X++ methods generating details and action pages

Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityContext</td>
<td>SysAppEntityContext</td>
<td>Entity context of the request</td>
</tr>
</tbody>
</table>
Method entityContext

Entity context of the request

```java
public SysAppEntityContext entityContext ([SysAppEntityContext _entityContext])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_entityContext</td>
<td>SysAppEntityContext</td>
<td>True</td>
<td>Entity context of the request</td>
</tr>
</tbody>
</table>

**Return Value**

Entity context of the request

Method filterContext

List of SysAppFilterContext for filter contexts

```java
public List filterContext ([List _filterContext])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_filterContext</td>
<td>List</td>
<td>True</td>
<td>List of SysAppFilterContext for filter contexts of page</td>
</tr>
</tbody>
</table>

**Return Value**

List of SysAppFilterContext for filter contexts of page

Class SysAppResponse

SysAppResponse class. This class holds the response object for generated pages and actions

**Methods**

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td></td>
</tr>
<tr>
<td>jobId</td>
<td>str</td>
<td>Job ID of the request</td>
</tr>
<tr>
<td>failedInAppCall</td>
<td>boolean</td>
<td>Data of the page</td>
</tr>
<tr>
<td>commits</td>
<td>List</td>
<td>Commits after task is completed</td>
</tr>
<tr>
<td>METHOD NAME</td>
<td>RETURNS</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-------------</td>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>messages</td>
<td>List</td>
<td>Job ID of the request</td>
</tr>
<tr>
<td>addMessage</td>
<td>void</td>
<td>Adds message</td>
</tr>
<tr>
<td>addCommit</td>
<td>void</td>
<td>Adds commits</td>
</tr>
</tbody>
</table>

**Method new**

```java
public void new ()
```

**Method jobId**

Job ID of the request

```java
public str jobId ()
```

**Return Value**

jobId of the request

**Method data**

Data of the page

```java
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
</table>

**Return Value**

Data of the page

**Method failedInAppCall**

Data of the page

```java
public boolean failedInAppCall ([boolean _failedInAppCall])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_failedInAppCall</td>
<td>boolean</td>
<td>True</td>
<td>Sets to true if it fails in calling application code</td>
</tr>
</tbody>
</table>

**Return Value**

True when fails in calling application code

**Method commits**
Commits after task is completed

```java
public List commits ()
```

**Return Value**
Commits after task is completed

**Method messages**
Job ID of the request

```java
public List messages ()
```

**Return Value**
Messages after task is completed

**Method addMessage**
Adds message

```java
public void addMessage (SysAppResponseMessage _message)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_message</td>
<td>SysAppResponseMessage</td>
<td>False</td>
<td>message as SysAppResponseMessage object</td>
</tr>
</tbody>
</table>

**Method addCommit**
Adds commits

```java
public void addCommit (SysAppEntityContext _entityContext)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_entityContext</td>
<td>SysAppEntityContext</td>
<td>False</td>
<td>Entity context containing entity name and entity ID of the entity that is</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>committed</td>
</tr>
</tbody>
</table>

**Class SysAppResponseMessage**
SysAppResponseMessage class for response messages

**Methods**

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppResponseMessage class</td>
</tr>
</tbody>
</table>
Method new
Creates a new instance of SysAppResponseMessage class

```java
public void new (str _text, [SysAppMessage _type])
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_text</td>
<td>str</td>
<td>False</td>
<td>The message text</td>
</tr>
<tr>
<td>_type</td>
<td>SysAppMessageType</td>
<td>True</td>
<td>Message Type: info, error, warning</td>
</tr>
</tbody>
</table>

Method text
Gets the message text

```java
public str text ()
```

Return Value
The message text

Method type
Gets the message type: info, error, warning

```java
public SysAppMessageType type ()
```

Return Value
The message type: info, error, warning

Class SysAppSecurityAttribute

SysAppSecurityAttribute used for decorating methods forming pages and actions. specifies security attribute of page or action

Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of SysAppSecurityAttribute class. This will help in checking if the user logged in has access to the specified menu item and menu item type</td>
</tr>
<tr>
<td>menuItemType</td>
<td>MenuItemType</td>
<td>Gets the Menu Item Type of the page</td>
</tr>
</tbody>
</table>
Method `new`  
Creates a new instance of `SysAppSecurityAttribute` class. This will help in checking if the user logged in has access to the specified menu item and menu item type

```java
public void new ([MenuItemName _menuItemName], [MenuItemType _menuItemType])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_menuItemName</td>
<td>MenuItemName</td>
<td>True</td>
<td>Menu Item Name of the page</td>
</tr>
<tr>
<td>_menuItemType</td>
<td>MenuItemType</td>
<td>True</td>
<td>Menu Item Type of the page like action, display, or output</td>
</tr>
</tbody>
</table>

Method `menuItemType`  
Gets the Menu Item Type of the page

```java
public MenuItemType menuItemType ()
```

Return Value  
Menu Item Type of the page

Method `menuItemName`  
Gets the Menu Item Name of the page

```java
public MenuItemName menuItemName ()
```

Return Value  
Menu Item Name of the page

**Class SysAppWorkspace**

This is the base class of mobile workspace. Mobile workspace classes need to extend from this class

**Methods**

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>getEnumValues</td>
<td>List</td>
<td>Called during workspace initialization. Can be used to modify the enum values that are returned to AX mobile</td>
</tr>
<tr>
<td>getWorkspaceMetadata</td>
<td>SysAppWorkspaceMetadata</td>
<td>Called during workspace initialization. Can be used to modify the workspace metadata</td>
</tr>
<tr>
<td>METHOD NAME</td>
<td>RETURNS</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>onBeginAppJob</td>
<td>void</td>
<td>Called before the start of execution of AX mobile job</td>
</tr>
<tr>
<td>onEndAppJob</td>
<td>void</td>
<td>Called after the end of execution of AX mobile job</td>
</tr>
<tr>
<td>workspaceHidden</td>
<td>boolean</td>
<td>Can be used to control whether the workspace is hidden or not. Checks that the current user has access menu item specified by SysAppWorkspaceSecurityAttribute on the workspace class. If the attribute is not specified on the class then it always returns false</td>
</tr>
</tbody>
</table>

**Method getEnumValues**

Called during workspace initialization. Can be used to modify the enum values that are returned to AX mobile

```java
public List getEnumValues (EnumName _enumName)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_enumName</td>
<td>EnumName</td>
<td>False</td>
<td>The enum name</td>
</tr>
</tbody>
</table>

**Return Value**

A list of enum value

**Method getWorkspaceMetadata**

Called during workspace initialization. Can be used to modify the workspace metadata

```java
public SysAppWorkspaceMetadata getWorkspaceMetadata ()
```

**Return Value**

An object representing the workspace metadata

**Method onBeginAppJob**

Called before the start of execution of AX mobile job

```java
public void onBeginAppJob (SysAppJobRequest _sysAppJobRequest)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_sysAppJobRequest</td>
<td>SysAppJobRequest</td>
<td>False</td>
<td>A class containing job request parameters</td>
</tr>
</tbody>
</table>

**Method onEndAppJob**

Called after the end of execution of AX mobile job
public void onEndAppJob (SysAppJobResponse _sysAppJobResponse)

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_sysAppJobResponse</td>
<td>SysAppJobResponse</td>
<td>False</td>
<td>A class containing job response parameters</td>
</tr>
</tbody>
</table>

Method `workspaceHidden`

Can be used to control whether the workspace is hidden or not. Checks that the current user has access menu item specified by `SysAppWorkspaceSecurityAttribute` on the workspace class. If the attribute is not specified on the class then it always returns false.

```java
public boolean workspaceHidden ()
```

Return Value

Returns true if the workspace is hidden otherwise false.

Class `SysAppWorkspaceAttribute`

Applied on classes that are extended from `SysAppWorkspace`

Methods

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>new</code></td>
<td>void</td>
<td>Creates a new instance of <code>SysAppWorkspaceAttribute</code> class</td>
</tr>
<tr>
<td>AppId</td>
<td>str</td>
<td>Gets or sets the AppId of the workspace</td>
</tr>
<tr>
<td>AppResourceName</td>
<td>str</td>
<td>Gets or sets the AOT Resource name that contains the workspace</td>
</tr>
<tr>
<td>WorkspaceHidden</td>
<td>boolean</td>
<td>Gets or sets if the workspace is hidden from designer</td>
</tr>
</tbody>
</table>

Method `new`

Creates a new instance of `SysAppWorkspaceAttribute` class

```java
public void new (str _appId, [str _appResourceName], [boolean _workspaceHidden])
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_appId</td>
<td>str</td>
<td>False</td>
<td>The appId of the workspace</td>
</tr>
<tr>
<td>_appResourceName</td>
<td>str</td>
<td>True</td>
<td>The AOT resource name that contains the workspace</td>
</tr>
</tbody>
</table>
### Method AppId
Gets or sets the AppId of the workspace

```java
public str AppId ([str _appId])
```

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_appId</td>
<td>str</td>
<td>True</td>
<td>The AppId of the workspace</td>
</tr>
</tbody>
</table>

**Return Value**
The AppId of the workspace

### Method AppResourceName
Gets or sets the AOT Resource name that contains the workspace

```java
public str AppResourceName ([str _appResourceName])
```

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_appResourceName</td>
<td>str</td>
<td>True</td>
<td>The AOT Resource name that contains the workspace</td>
</tr>
</tbody>
</table>

**Return Value**
The AOT Resource name that contains the workspace

### Method WorkspaceHidden
Gets or sets if the workspace is hidden from designer

```java
public boolean WorkspaceHidden ([boolean _workspaceHidden])
```

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_workspaceHidden</td>
<td>boolean</td>
<td>True</td>
<td>The workspace hidden</td>
</tr>
</tbody>
</table>

**Return Value**
Whether the workspace is hidden from designer or not

### Class SysAppWorkspaceMetadata
This class can be used to access and update metadata of an AX mobile workspace

### Methods
<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td></td>
</tr>
<tr>
<td>addConfig</td>
<td>void</td>
<td>Adds a custom config to the mobile workspace metadata</td>
</tr>
<tr>
<td>getPage</td>
<td>SysAppPageMetadata</td>
<td>Returns the page with the pageName provided</td>
</tr>
<tr>
<td>getPageEnumerator</td>
<td>MapEnumerator</td>
<td>Returns a map enumerator that can be used to enumerate workspace pages. Where key is page name and value is of type SysAppPageMetadata</td>
</tr>
<tr>
<td>getPageNameForRecordingId</td>
<td>str</td>
<td>Returns a pageName if the provided recordingId is used by a workspace page</td>
</tr>
<tr>
<td>getPageNameForRecordingId</td>
<td>str</td>
<td>Returns an actionName if the provided recordingId is used by a workspace action</td>
</tr>
<tr>
<td>workspaceTitle</td>
<td>str</td>
<td>Gets and sets the workspace title</td>
</tr>
<tr>
<td>workspaceDescription</td>
<td>str</td>
<td>Gets and sets the workspace description</td>
</tr>
</tbody>
</table>

**Method new**

```
public void new (str _appId, [SysAppWorkspaceAttribute _attribute])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_appId</td>
<td>str</td>
<td>False</td>
<td></td>
</tr>
<tr>
<td>_attribute</td>
<td>SysAppWorkspaceAttribute</td>
<td>True</td>
<td></td>
</tr>
</tbody>
</table>

**Method addConfig**

Adds a custom config to the mobile workspace metadata

```
public void addConfig (str _configName, object _configValue)
```

**Parameters**
Method getPage

Returns the page with the pageName provided

```java
public SysAppPageMetadata getPage (str _pageName)
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_pageName</td>
<td>str</td>
<td>False</td>
<td>A page name</td>
</tr>
</tbody>
</table>

Return Value

Returns the pageMetadata if a page with the provided name exists; otherwise null

Method getPageEnumerator

Returns a map enumerator that can be used to enumerate workspace pages. Where key is page name and value is of type SysAppPageMetadata

```java
public MapEnumerator getPageEnumerator ()
```

Return Value

A map enumerator

Method getAction

Returns the action with the actionName provided

```java
public SysAppActionMetadata getAction (str _actionName)
```

Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_actionName</td>
<td>str</td>
<td>False</td>
<td>An action name</td>
</tr>
</tbody>
</table>

Return Value

Returns the ActionMetadata if an action with the provided name exists; otherwise null

Method getActionEnumerator

Returns a map enumerator that can be used to enumerate workspace actions. Where key is action name and value is of type SysAppActionMetadata

```java
public MapEnumerator getActionEnumerator ()
```

Return Value

A map enumerator
**Method getPageNameForRecordingId**

Returns a pageName if the provided recordingId is used by a workspace page

```java
public str getPageNameForRecordingId (str _recordingId)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_recordingId</td>
<td>str</td>
<td>False</td>
<td>A recordingId</td>
</tr>
</tbody>
</table>

**Return Value**

A page name if the supplied recordingId is used by a workspace page; otherwise empty string

**Method getActionNameForRecordingId**

Returns a actionName if the provided recordingId is used by a workspace action

```java
public str getActionNameForRecordingId (str _recordingId)
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_recordingId</td>
<td>str</td>
<td>False</td>
<td>A recordingId</td>
</tr>
</tbody>
</table>

**Return Value**

An action name if the supplied recordingId is used by a workspace action; otherwise empty string

**Method workspaceTitle**

Gets and sets the workspace title

```java
public str workspaceTitle ([str _workspaceTitle])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_workspaceTitle</td>
<td>str</td>
<td>True</td>
<td>The workspace title</td>
</tr>
</tbody>
</table>

**Return Value**

The workspace title

**Method workspaceDescription**

Gets and sets the workspace description

```java
public str workspaceDescription ([str _workspaceDescription])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_workspaceDescription</td>
<td>str</td>
<td>True</td>
<td>The workspace description</td>
</tr>
</tbody>
</table>

**Return Value**
The workspace description

**Class SysAppWorkspaceSecurityAttribute**

Controls the visibility based of workspace based on the menu item tied to this attribute

**Methods**

<table>
<thead>
<tr>
<th>METHOD NAME</th>
<th>RETURNS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>void</td>
<td>Creates a new instance of attribute</td>
</tr>
<tr>
<td>WorkspaceMenuItemName</td>
<td>MenuItemName</td>
<td>Gets or sets the workspace menuitem for the workspace security attribute</td>
</tr>
<tr>
<td>WorkspaceMenuItemType</td>
<td>MenuItemType</td>
<td>Gets or sets the workspace menu item type for the workspace security attribute</td>
</tr>
</tbody>
</table>

**Method new**

Creates a new instance of attribute

```java
public void new (MenuItemName _workspaceMenuItemName, [MenuItemType _workspaceMenuItemType])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_workspaceMenuItemName</td>
<td>MenuItemName</td>
<td>False</td>
<td>The menu item name to which the workspace needs to be tied</td>
</tr>
<tr>
<td>_workspaceMenuItemType</td>
<td>MenuItemType</td>
<td>True</td>
<td>The menu item type</td>
</tr>
</tbody>
</table>

**Method WorkspaceMenuItemName**

Gets or sets the workspace menuitem for the workspace security attribute

```java
public MenuItemName WorkspaceMenuItemName ([MenuItemName _workspaceMenuItemName])
```

**Parameters**

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_workspaceMenuItemName</td>
<td>MenuItemName</td>
<td>True</td>
<td>The workspace menu item for the workspace security attribute</td>
</tr>
</tbody>
</table>

**Return Value**

The workspace menu item for the workspace security attribute

**Method WorkspaceMenuItemType**

Gets or sets the workspace menu item type for the workspace security attribute

```java
public MenuItemType WorkspaceMenuItemType ([MenuItemType _workspaceMenuItemType])
```
## Parameters

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>PARAMETER TYPE</th>
<th>OPTIONAL</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>_workspaceMenuItemType</td>
<td>MenuItemType</td>
<td>True</td>
<td>The workspace menu item type for the workspacesecurity attribute</td>
</tr>
</tbody>
</table>

## Return Value

The workspace menu item type for the workspace security attribute.
This topic provides an overview of the application programming interfaces (APIs) for client-side design and includes recommendations for using them.

**Terminology**

The following list includes some frequently used terms that apply to the client-side design APIs.

- **Design** – A property that can optionally be specified on a Page, Action, or other component object to override its default design.

- **Component** – A component can be one of four types:
  - **Block container** (default) – A container that has CSS block behaviors. (In other words, the container is equivalent to an element that has a CSS `display: block` style declaration.)
  - **Flex container** – A container that has CSS flex behaviors. (In other words, the container is equivalent to an element that has a CSS `display: flex` style declaration.)
  - **Control reference** – A component that refers to a control that exists in the static metadata (XML) of the Page or Action.
  - **New control** – A component that instantiates a new control. (In other words, the control doesn’t already exist in the static metadata [XML] of the Page or Action.)

  A component is represented in the design by a JavaScript Object Notation (JSON) object, and the properties of this JSON object represent the properties of the component. Almost every JSON object in the design property hierarchy is a component.

- **Item** – A component that is nested in a container.

- **Property** – Several types of properties can be set on a component:
  - Container-specific
  - Item-specific
  - Control-specific
  - List-specific
  - Generic (non-specific)

  Properties are specified as key-value pairs on the component’s JSON object. The properties that are applicable depend on the type of component that the property is applied to.

  For properties that have a predefined list of possible values, the first value that is shown in the documentation is the property’s default value. In most cases, if you don’t specify a property at all (that is, if you omit the property from the JSON object), the property behaves as if you had set its default value.

  Generic properties can be applied to all component types.

  When you specify properties, follow these guidelines:
You should not enclose property names in quotation marks.

You must enclose all property values in double quotation marks, unless the documentation specifies otherwise.

- **Inheritance** – If a color, font size, or font weight is applied to a control, all descendant controls inherit the same property, unless they are reassigned. If padding is applied to a control, it’s inherited by the item (non-container) descendants of the control. No other properties are inherited.

### Using design APIs

The following code is a modified segment of business logic code from a Reservation Management example. Specifically, this code is from a variable that specifies the design for a reservation details page. Comments are included in the code to highlight a few possibilities.

```plaintext
NOTE

Any color, font size, or font weight that is applied to a control is also applied to all children of that control. Padding is inherited by non-container children. No other properties are inherited. Containers include lists, pages, groups, and parts.

After a control is created that doesn't have any children or items, the control name just has to be written in quotation marks (see `FMCustomer_FullName` in the following code). However, if any customization will be applied to that control, the code must be blocked, and the **name** label must be used (see `FMCustomer_Image` in the following code).
```
The following illustration shows the customer image, customer name, font, background color, and so on, that preceding code produces.

Enumeration members

error
error: 10 The page is currently in the error state, but can be refreshed in an attempt to get out of this state.

loaded
loaded: 3 The page is fully loaded and can be refreshed and, if possible, submitted.

loading
loading: 2 The page is currently being loaded.

offline
offline: 1 The page was loaded in the offline mode, thus not refreshable.

refreshing
refreshing: 4 The page is currently refreshing its data.
An application is a unit of runtime execution with sandboxing around concepts and data used inside of it. Each application consists of pages, actions, data queries, and logic that glue them together. An application is primarily described with a declarative metadata system, and can have an accompanying imperative extension model.

The imperative extension of the application is typically defined in a script module with a designated entry point, the `main function`, which allows the imperative logic to integrate with the application life cycle.

Functions

**main**

```plaintext
```

The main method of a business logic module. Each business logic module (as JavaScript file) must contain one main method. The method is invoked when the module is loaded and is being initialized. The method must return the component to run from this module.

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>

ContainerControlDesign

|-- ListDesign

### Properties

<table>
<thead>
<tr>
<th>NAME</th>
<th>SIGNATURE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>alignItems</td>
<td>alignItems: string (optional)</td>
<td>This property is an alias for the CSS property &quot;align-items&quot;. Inherited from Design.alignItems</td>
</tr>
<tr>
<td>alignSelf</td>
<td>alignSelf: string (optional)</td>
<td>Inherited from Design.alignSelf</td>
</tr>
<tr>
<td>allowScroll</td>
<td>allowScroll: string (optional)</td>
<td>True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas. Inherited from ContainerControlDesign.allowScroll</td>
</tr>
<tr>
<td>background</td>
<td>background: string (optional)</td>
<td>The background color of the container. Inherited from ContainerControlDesign.background</td>
</tr>
<tr>
<td>bindings</td>
<td>bindings: any (optional)</td>
<td>Inherited from Design.bindings</td>
</tr>
<tr>
<td>border</td>
<td>border: &quot;none&quot;</td>
<td>&quot;solid&quot;</td>
</tr>
<tr>
<td>color</td>
<td>color: string (optional)</td>
<td>The foreground color of the container. Inherited from Design.color</td>
</tr>
<tr>
<td>design</td>
<td>design: GroupDesign (optional)</td>
<td>The design object that will be applied to each row.</td>
</tr>
<tr>
<td>flexFlow</td>
<td>flexFlow: string (optional)</td>
<td>Specifying this property makes the component a flex container component. Inherited from Design.flexFlow</td>
</tr>
<tr>
<td>flexSize</td>
<td>flexSize: string (optional)</td>
<td>One number or two numbers written as a string. For example, &quot;(size to grow) [(size-to-shrink)]&quot; to accommodate available space in the immediate flex container. Inherited from Design.flexSize</td>
</tr>
<tr>

<tr>
<td>generic</td>
<td>generic: boolean (optional)</td>
<td>Inherited from <code>Control.generic</code></td>
</tr>
<tr>
<td>getDataSource</td>
<td>getDataSource: function(): any</td>
<td>Inherited from <code>Control.getDataSource</code></td>
</tr>
<tr>
<td>hidden</td>
<td>hidden: boolean</td>
<td>True if the control is hidden.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Inherited from <code>Control.hidden</code></td>
</tr>
</tbody>
</table>

### Methods

<table>
<thead>
<tr>
<th>NAME</th>
<th>SIGNATURE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>applyDesign</td>
<td>applyDesign(IDesign: LookupDesign): void</td>
<td>Applies given design to the design on the control. Overrides <code>Control.applyDesign</code></td>
</tr>
<tr>
<td>dataContext</td>
<td>dataContext(): any</td>
<td>Inherited from <code>Control.dataContext</code></td>
</tr>
<tr>
<td>getDesign</td>
<td>getDesign(): Design</td>
<td>Returns the design object of this control.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Inherited from <code>Control.getDesign</code></td>

<tr>
<td>getDisplayValue</td>
<td>getDisplayValue(): string</td>
<td></td>
</tr>
<tr>
<td>getLookupPage</td>
<td>getLookupPage(): Page</td>
<td></td>
</tr>
</tbody>
</table>
### getValue

getValue(): string | number

**Description**

Boolean indicating if the control is editable. Inherited from Control.isEditable

### isEditable

isEditable(): boolean

**Description**

Boolean indicating if the control is editable. Inherited from Control.isEditable

### metadata

metadata(): LookupMetadata

**Description**

Returns the metadata object of this control. Overrides InputControl.metadata

### parent

parent(): Control | Page

**Description**

Returns the parent (control or page) of this control. Inherited from Control.parent

### root

root(): Page

**Description**

Returns the root form instance (page) of this control. Inherited from Control.root

### setEntityRef

setEntityRef(newValue: string | number): Promise <any>

### Events

**onDataChanged**

onDataChanged: EventHook <null>

**Description**

An event that is triggered when the input control's data changes. Inherited from InputControl.onDataChanged

### LookupDesign

**Hierarchy**

- InputControlDesign
  - LookupDesign

### Properties

<table>
<thead>
<tr>
<th>NAME</th>
<th>SIGNATURE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>alignItems</td>
<td>alignItems: string (optional)</td>
<td>This property is an alias for the CSS property &quot;align-items&quot;. Inherited from Design.alignItems</td>
</tr>
<tr>
<td>alignSelf</td>
<td>alignSelf: string (optional)</td>
<td>Inherited from Design.alignSelf</td>
</tr>

<td>Inherited from Design.bindings</td>
</tr>
<tr>
<td>border</td>
<td>border: &quot;none&quot;</td>
<td>&quot;solid&quot;</td>
</tr>
<tr>
<td>color</td>
<td>color: string (optional)</td>
<td>The foreground color of the container. Inherited from Design.color</td>
</tr>
</tbody>
</table>
### flexFlow

**Signature**: `flexFlow: string (optional)`  
**Description**: Specifying this property makes the component a flex container component. Inherited from `Design.flexFlow`

### flexSize

**Signature**: `flexSize: string (optional)`  
**Description**: One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. Inherited from `Design.flexSize`

### fontSize

**Signature**: `fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)`  
**Description**: The proportional text size. Inherited from `Design.fontSize`

### fontWeight

**Signature**: `fontWeight: "normal" | "bold" (optional)`  
**Description**: Normal or bold text. Inherited from `Design.fontWeight`

### justifyItems

**Signature**: `justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)`  
**Description**: This property is an alias for the CSS property "justify-content". Inherited from `Design.justifyItems`

### label

**Signature**: `label: string (optional)`  
**Description**: Inherited from `Design.label`

### labelPosition

**Signature**: `labelPosition: "stacked" | "hidden" | "inline" (optional)`  
**Description**: Determines how a label is positioned, if at all. By default, labelPosition is set to stacked. Inherited from `Design.labelPosition`

### name

**Signature**: `name: string (optional)`  
**Description**: Inherited from `Design.name`

### padding

**Signature**: `padding: "none" | "small" | "std" (optional)`  
**Description**: Allows specifying the component's padding behavior. Inherited from `Design.padding`

### type

**Signature**: `type: ControlType (optional)`  
**Description**: The type of the control as a string. Inherited from `Design.type`

Multi-Lookup controls are similar to regular lookups except they allow multiple selections at once.
### getDesign

**getDesign()**: `Design`  
Returns the design object of this control. Inherited from `Control.getDesign`.

### getLookupPage

**getLookupPage()**: `Page`  

### isEditable

**isEditable()**: `boolean`  
Boolean indicating if the control is editable. Inherited from `Control.isEditable`.

### metadata

**metadata()**: `MultiLookupMetadata`  
Returns the metadata object of this control. Overrides `InputControl.metadata`.

### parent

**parent()**: `Control | Page`  
Returns the parent (control or page) of this control. Inherited from `Control.parent`.

### root

**root()**: `Page`  
Returns the root form instance (page) of this control. Inherited from `Control.root`.

### Events

<table>
<thead>
<tr>
<th>NAME</th>
<th>SIGNATURE</th>

<td></td>
</tr>
</tbody>
</table>
The IPage interface encapsulates the various properties, life cycle and event hooks associated with a page in a workspace.

**Page data Synchronization**

Pages that can submit changes (also referred to as actions) go through various stages before they’re completely in sync with the server. As soon as a page is submitted, there are three possible consequences:

- It fails client-side validation: The client logic might prevent the page from being submitted.
- The client is online: The submission is processed as soon as the application-wide sync queue is cleared.
- The client is offline: The submission is added to the application-wide sync queue and stays there as long as the client is offline.

While a submission is waiting to be synchronized, it can be in one of these states:

- Pending: The submission is still pending and can still be edited.
- Processing: The submission is currently being synchronized. In this state, any further edits are not allowed on the page.

After a submission goes through to the server, it can be in one of these states:

- Synchronized: The submission is accepted by the server and is synchronized.
- Error: The server rejects the submission and the page enters an error state.

Multiple pending submissions for a given page and context might be clubbed (and sent) together if the page is deemed to be idempotent. This implies that the server need not process all submissions in any order and depends on the design of the page on the server.

<td>items: string</td>
<td>Design [ ] (optional)</td>
</tr>
</tbody>
</table>
### justifyItems

**justyItems**: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Inherited from **Design.justifyItems**

### label

**label**: string (optional)

Inherited from **Design.label**

### labelPosition

**labelPosition**: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked. Inherited from **Design.labelPosition**

### name

**name**: string (optional)

Inherited from **Design.name**

### padding

**padding**: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. Inherited from **Design.padding**

### target

**target**: PageTarget (optional)

Target page of the part.

### type

**type**: ControlType (optional)

The type of the control as a string. Inherited from **Design.type**

</table>
### configureWorkspace

configureWorkspace(options: PageMetadata): any

Configuring a workspace allows specifying or overriding certain behaviors specific to the workspace.

### findAction

findAction(actionName: string): PageMetadata

Gets a copy of the current metadata instance of a specified Action, for the purpose of inspecting the metadata (not to be used for changing the metadata).

### findControl

findControl(componentMetadata: any, controlName: string): ControlMetadata

Gets a copy of the current metadata instance of a specified control, for the purpose of inspecting the metadata (not to be used for changing the metadata).

### findPage

findPage(pageName: string): PageMetadata

Gets a copy of the current metadata instance of a specified page, for the purpose of inspecting the metadata (not to be used for changing the metadata).

### getFilterExpression

getFilterExpression(pageName: string, listControlName: string, controlName: string, operator: ExpressionOperator, value: string): DataFilter

Create a DataFilter object for a list control based on the provided options.

### getFormReference

getFormReference(componentName: string, filterContext: DataFilter, excludeContext: boolean, filterLocalOnly?: boolean): NavigationArgs

Create an INavigationArgs object for a specific page action to be used with a navigation control.

### hideNavigation

hideNavigation(pageNamesToHide: string[]): any

Hides the specified page(s) from the default landing page.

### PageData

<tr>
<td>setControlValue</td>
<td>setControlValue(controlName: string, value: any): any</td>
<td>Sets the value of a control directly into the data set loaded in the page.</td>
</tr>
</tbody>
</table>

### Type aliases

**ExpressionOperator**

ExpressionOperator: "Is" | "IsNot" | "Contains" | "BeginsWith" | "EndsWith" | "GreaterThan" | "LessThan" | "GreaterThanOrEqual" | "LessThanOrEqual"
Represents possible values for the expression operator used in defining filters and in other places
This is the base class for single value controls.

**Methods**
applyDesign

applyDesign(design: Design): void
Applies given design to the design on the control. Inherited from Control.applyDesign

dataContext
dataContext(): any
Inherited from Control.dataContext

getDesign
getDesign(): Design
Returns the design object of this control. Inherited from Control.getDesign

getValue
getValue(): string
Returns the value of the control.

isEditable
isEditable(): boolean
Boolean indicating if the control is editable. Inherited from Control.isEditable

metadata
metadata(): ValueMetadata
Returns the metadata object of this control. Overrides InputControl.metadata

parent
parent(): Control | Page
Returns the parent (control or page) of this control. Inherited from Control.parent

root
root(): Page
Returns the root form instance (page) of this control. Inherited from Control.root

setValue
setValue(value: string): void
Sets the value of the control.

Events

onDataChanged
onDataChanged: EventHook <null>
An event that is triggered when the input control's data changes. Inherited from InputControl.onDataChanged

</tbody>
</table>
Represents a runtime instance of an application.

Hierarchy
Application

Index
Properties
- minVersion

Methods
- appInit

Properties

minVersion

minVersion: string (optional)

An optional marker to indicate the minimum platform version required by this component. When this is specified and the component is attempted to be loaded in an older version of the platform, the corresponding workspace is not loaded and user is directed to install a newer version of the platform.

Methods

appInit

appInit(metadata: ApplicationMetadata): any

This method is invoked at the point the application is about to run, with the instance of the application metadata loaded. The metadata passed in can be still modified to change behaviors before this method returns.

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata</td>
<td>ApplicationMetadata</td>
<td></td>
</tr>
</tbody>
</table>

Returns any
Represents the declarative metadata of an application

**Hierarchy**
ApplicationMetadata

**Index**

**Properties**
- **ColorName**
  - ColorName: string (optional)
  - The theme color of the application
- **Configs**
  - Configs: {name: string}: any (optional)
  - An application can have a set of named config supplied by the author or the resource provider
- **Description**
  - Description: string (optional)
  - The description of the application
- **IconName**
  - IconName: string (optional)
  - The representative icon of the application
- **Id**
  - Id: string
  - The unique identifier of the application
- **Title**
  - Title: string
  - The title of the application
AsyncService type

Provides ability to perform async operations from business logic code.

**Hierarchy**
AsyncService

**Index**

**Method list**
- all
- defer

**Methods**

**all**

```typescript
all(...args: any[]): Promise<any[]>
```

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>...args</td>
<td>any[]</td>
<td></td>
</tr>
</tbody>
</table>

**Returns** Promise <any[]>

**defer**

```typescript
defer(): Deferred<T>
```

Creates a deferred object that can be used to return a promise from event handlers (where applicable) and resolve/reject them asynchronously.

**Returns** Deferred <T>
Provides ability to access data from the device cache and update data into the device cache.

Properties

error
error: boolean (optional)

navigation
navigation: NavigationArgs (optional)

processed
processed: boolean (optional)
Container control interface with methods and attributes for all container controls. A container control can contain any number of controls.

Hierarchy

Control
└ ContainerControl
  └ Group
  └ List
  └ Part

Index

Properties

• container
• generic
• getDataSource
• hidden

Methods

• applyDesign
• dataContext
• getControl
• getControlById
• getDesign
• isEditable
• metadata
• parent
• root

Properties

container
container: boolean

True if the control is a container.

Overrides Control.container

generic
generic: boolean (optional)

Inherited from Control.generic

getDataSource
gDataSource: function(): any
Inherited from `Control.getDataSource`

**hidden**

hidden: boolean

True if the control is hidden.

Inherited from `Control.hidden`

## Methods

**applyDesign**

`applyDesign(design: Design): void`

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Inherited from `Control.applyDesign`

### Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>design</td>
<td>Design</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void

**dataContext**

dataContext(): any

Inherited from `Control.dataContext`

Returns any

**getControl**

getControl(controlName: string): `Control`

Given the name of a control, returns the control instance.

### Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td>control name</td>
</tr>
</tbody>
</table>

Returns `Control`

**getControlById**

getControlById(id: string): `Control`

Given the ID of a control, returns the control instance.

### Parameters
<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
<td>control ID</td>
</tr>
</tbody>
</table>

Returns *Control*

**getDesign**

getDesign(): *Design*

Returns the design object of this control.

Inherited from *Control.getDesign*

Returns *Design*

**isEditable**

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

Inherited from *Control.isEditable*

Returns boolean

**metadata**

metadata(): *ContainerControlMetadata*

Returns the metadata object of this control.

Overrides *Control.metadata*

Returns *ContainerControlMetadata*

**parent**

parent(): *Control | Page*

Returns the parent (control or page) of this control.

Inherited from *Control.parent*

Returns *Control | Page*

**root**

root(): *Page*

Returns the root form instance (page) of this control.

Inherited from *Control.root*

Returns *Page*
Container control design object has properties specific to all container controls.

Hierarchy

Index

Properties

- alignItems
- alignSelf
- allowScroll
- background
- bindings
- border
- color
- flexFlow
- flexSize
- fontSize
- fontWeight
- itemBorderStyle
- items
- justifyItems
- label
- labelPosition
- name
- padding
- type

Properties

**alignItems**

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

Inherited from **Design.alignItems**

**alignSelf**

alignSelf: string (optional)
allowScroll

allowScroll: string (optional)

True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.

background

background: string (optional)

The background color of the container. Consider modifying the color attribute in the same container so that fonts overlaying the background color will appear appropriately. Note: if background is set to "theme", the theme color of the app will be used. The following colors are available:

- blue: \#0078D7;
- pomegranate: \#911844;
- raspberry: \#8D398F;
- darkOrange: \#D24726;
- green: \#369F47;
- blueberry: \#17234E;
- grape: \#432158;
- lightBlue: \#5DB2FF;
- lightGreen: \#82BA00;
- pink: \#DC4FAD;
- teal: \#008299;
- mediumDarkBlue: \#004B8B;
- cordovan: \#570000;
- darkCordovan: \#380000;
- black: \#000000;
- lightGray: \#e8e8e8;
- light: \#fff;
- dark: \#333333;

bindings

bindings: any (optional)

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

color

color: string (optional)
The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.

Consider setting the background color at the same time as necessary when setting this attribute.

Note: if color is set to "theme", the theme color of the app will be used.

The following colors are available:

- blue: \#0078D7
- pomegranate: \#911844
- raspberry: \#8D398F
- darkOrange: \#D24726
- green: \#369F47
- blueberry: \#17234E
- grape: \#432158
- lightBlue: \#5DB2FF
- lightGreen: \#82BA00
- pink: \#DC4FAD
- teal: \#008299
- mediumDarkBlue: \#004B8B
- cordovan: \#570000
- darkCordovan: \#380000
- black: \#000000
- lightGray: \#e8e8e8
- light: \#fff
- dark: \#333333

Inherited from Design.color

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property “flex-flow”. Please refer to this web page for documentation on the “flex-flow” property.

Inherited from Design.flexFlow

flexSize

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the “flex” property.

Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size
Inherited from Design.fontSize

fontWeight
fontWeight: "normal" | "bold" (optional)
Normal or bold text.
Inherited from Design.fontWeight

itemBorder
itemBorder: "solid" | "none" (optional)
If true, a border will appear around each row in the list. This property is equivalent to applying the border property individually to all items in the container.

items
items: string | Design [] (optional)
An array containing the components to place inside of the container.

justifyItems
justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)
This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.
Inherited from Design.justifyItems

label
label: string (optional)
Inherited from Design.label

labelPosition
labelPosition: "stacked" | "hidden" | "inline" (optional)
Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.
Inherited from Design.labelPosition

name
name: string (optional)
Inherited from Design.name

padding
padding: "none" | "small" | "std" (optional)
Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.
Inherited from Design.padding

type
type: `ControlType` (optional)

The type of the control as a string.

Inherited from `Design.type`
Container control metadata type.

Properties

- **BoundEntity**
  The entity to which the control is bound.

- **BoundField**

- **Description**
  Description of the control.

- **Editable**

- **ExtType**

- **HelpText**

- **Hidden**

- **Id**

- **Label**

- **Name**

- **Order**

- **Type**

Properties

**BoundEntity**

BoundEntity: string (optional)

The entity to which the control is bound.

Inherited from **ControlMetadata.BoundEntity**

**BoundField**

BoundField: string (optional)

Inherited from **ControlMetadata.BoundField**

**Description**

Description: string (optional)

Description of the control.

Inherited from **ControlMetadata.Description**
**Editable**

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from `ControlMetadataEditable`

**ExtType**

ExtType: `ControlType` (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from `ControlMetadataExtType`

**HelpText**

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Inherited from `ControlMetadataHelpText`

**Hidden**

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Inherited from `ControlMetadataHidden`

**Id**

Id: string (optional)

Identification string for a control.

Inherited from `ControlMetadataId`

**Label**

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

Inherited from `ControlMetadataLabel`

**Name**

Name: string (optional)

Name of a control.

Inherited from `ControlMetadataName`

**Order**

Order: number (optional)
Number indicating the order in which a control will appear on a page.

Inherited from ControlMetadata.Order

**Type**

Type: ControlType (optional)

String indicating the control type.

Inherited from ControlMetadata.Type
Interface for the metadata of a control. Overriding control metadata can modify a controls' look and behavior. Properties that can be modified vary by control but every control will have the base properties listed here.

**Hierarchy**

BoundEntity: string (optional)

The entity to which the control is bound.

**BoundField**

BoundField: string (optional)

**Description**

Description: string (optional)

Description of the control.

**Editable**

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is
undefined. Undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

**ExtType**
ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

**HelpText**
HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

**Hidden**
Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

**Id**
Id: string (optional)

Identification string for a control.

**Label**
Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

**Name**
Name: string (optional)

Name of a control.

**Order**
Order: number (optional)

Number indicating the order in which a control will appear on a page.

**Type**
Type: ControlType (optional)

String indicating the control type.

### Methods

#### findEntityData

```
findEntityData(entityType: any, propertyName: string, propertyValue: any, includeChanges?: boolean): any
```

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityType</td>
<td>any</td>
<td></td>
</tr>
<tr>
<td>propertyName</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>propertyValue</td>
<td>any</td>
<td></td>
</tr>
<tr>
<td>includeChanges?</td>
<td>boolean</td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

any

#### getEntityData

```
getEntityData(entityType: any, entityId: string): any
```

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityType</td>
<td>any</td>
<td></td>
</tr>
<tr>
<td>entityId</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

any

#### getPageData

```
getPageData(pageId: string, context: any, filter: any, allowedStaleness: number): Promise <PageData>
```

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageId</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>context</td>
<td>any</td>
<td></td>
</tr>
<tr>
<td>filter</td>
<td>any</td>
<td></td>
</tr>
<tr>
<td>allowedStaleness</td>
<td>number</td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

Promise <PageData>
<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageld</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>context</td>
<td>any</td>
<td></td>
</tr>
<tr>
<td>filter</td>
<td>any</td>
<td></td>
</tr>
<tr>
<td>allowedStaleness</td>

Methods
- reject
- resolve

Properties

promise
promise: Promise <T>

Methods

reject
reject(error?: any): void

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>error?</td>
<td>any</td>
<td></td>
</tr>
</tbody>
</table>

Returns void

resolve
resolve(value?: T | PromiseLike <T>): void

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>value?</td>
<td>T</td>
<td>PromiseLike &lt;T&gt;</td>
</tr>
</tbody>
</table>

Returns void
Design object type. For more information on design, please reference the Design Introduction.

**Properties**

**alignItems**

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

**alignSelf**

alignSelf: string (optional)

**bindings**

bindings: any (optional)

**border**

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)
The border behavior of a control. This property will not be inherited by the children.

**color**
color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to “theme”, the theme color of the app will be used.

The following colors are available:

- **blue**: #0078D7;
- **pomegranate**: #911B44;
- **raspberry**: #8D398F;
- **darkOrange**: #D24726;
- **green**: #369F47;
- **blueberry**: #17234E;
- **grape**: #432158;

- **black**: #000000;
- **lightGray**: #e8e8e8;
- **light**: #fff;
- **dark**: #333333;

**flexFlow**
flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property “flex-flow”. Please refer to this web page for documentation on the “flex-flow” property.

**flexSize**
flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the “flex” property.

**fontSize**
fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

**fontWeight**
fontWeight: "normal" | "bold" (optional)
Normal or bold text.

**justifyItems**
justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

**label**
label: string (optional)

**labelPosition**
labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

**name**
name: string (optional)

**padding**
padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

**type**
type: ControlType (optional)

The type of the control as a string.

Methods

• subscribe
• unsubscribe
• unsubscribeAll

Methods

subscribe
subscribe(listener: IEventListener<T>): void

Subscribe a listener to this event.

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>listener</td>
<td>IEventListener&lt;T&gt;</td>
<td></td>
</tr>
</tbody>
</table>

Returns void

unsubscribe
unsubscribe(listener: IEventListener<T>): void

Unsubscribe a listener from this event.

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>listener</td>
<td>IEventListener&lt;T&gt;</td>
<td></td>
</tr>
</tbody>
</table>

Returns void

unsubscribeAll
unsubscribeAll(): void

Remove all listeners from this event.

Returns void
Field control type.

generic: boolean (optional)

Inherited from `Control.generic`

**getDataSource**

getDataSource: function(): any

Inherited from `Control.getDataSource`

**hidden**

hidden: boolean

True if the control is hidden.

Inherited from `Control.hidden`

## Methods

### applyDesign

**applyDesign**(IDesign: `FieldDesign`): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides `Control.applyDesign`

### Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDesign</td>
<td><code>FieldDesign</code></td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

**Returns void**

### dataContext

**dataContext**(): any

Inherited from `Control.dataContext`

**Returns any**

### getDesign

**getDesign**(): `Design`

Returns the design object of this control.

Inherited from `Control.getDesign`

**Returns Design**

### getEditableFormattedValue

**getEditableFormattedValue**(): string | number | Date

Gets a formatted decimal string value of an editable field control.
getEditableValue

getEditableValue(): string | number | Date

Gets the value for an editable field control.

getEntityRef

getEntityRef(): any

Gets value of entityRef binding to control.

getFormattedValue

getFormattedValue(): string

Gets a formatted decimal string value.

getRefLink

getRefLink(): NavigationArgs

Gets the navigation object for a reference link.

getValue

getValue(): any

Gets the value for a field control.

hasRefLink

hasRefLink(): boolean

Returns true if the field has a refLink, otherwise false.

hasUnWrapText

hasUnWrapText(): boolean

Gets wrap text property of control.

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

Inherited from Control.isEditable

Returns boolean
metadata

metadata(): FieldMetadata

Returns the metadata object of this control.

| Overides InputControl.metadata |

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

| Inherited from Control.parent |

root

root(): Page

Returns the root form instance (page) of this control.

| Inherited from Control.root |

setEditableValue

setEditableValue(value: string | number | Date): void

Sets the value for an editable field control.

| Parameters |
| NAME | TYPE | DESCRIPTION |
| value | string | number | Date | value |

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

| Inherited from InputControl.onDataChanged |
Design object interface for a field control.

**Hierarchy**

- **dark**: #333333;

Inherited from Design.color

**flexFlow**

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

Inherited from Design.flexFlow

**flexSize**

flexSize: string (optional)
One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

Inherited from Design.flexSize

**fontSize**

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

Inherited from Design.fontSize

**fontWeight**

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

Inherited from Design.fontWeight

**justifyItems**

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

Inherited from Design.justifyItems

**label**

label: string (optional)

Inherited from Design.label

**labelPosition**

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

Inherited from Design.labelPosition

**name**

name: string (optional)

Inherited from Design.name

**padding**

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

Inherited from Design.padding
**type**

Type: `ControlType` (optional)

The type of the control as a string.

Inherited from `Design.type`
Interface for field metadata.

Hierarchy

- Type
- UnWrapText
- WrapText

Properties

**BoundEntity**

BoundEntity: string (optional)

The entity to which the control is bound.

Inherited from ControlMetadata.BoundEntity
DecimalPlaces

DecimalPlaces: number (optional)

The number of decimals that appear on a field of type "Real". Default = 2; number must be in the range [0:20].

Description

Description: string (optional)

Description of the control.

Editable

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

ExtType

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

Formatting

Formatting: any (optional)

Formats a field of type "DateTime" or "Date". **Note**: if browser does not support `toLocaleString` with options then it will show the entire value.

The options for Formatting depends on the Style that has been chosen: Style: "DateOnly" options, Style: "TimeOnly" options, and options for no style.

Example 1: `{ Style: "TimeOnly", Formatting: { timeZone: "UTC", timeZoneName: "short" } }`

Example 2: `{ Style: "DateOnly", Formatting: { month: "long", day: "numeric" } }` result: March 2

HelpText

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Hidden

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.
| Inherited from **ControlMetadata.Hidden** |

**Id**
Id: string (optional)
Identification string for a control.
| Inherited from **ControlMetadata.Id** |

**Label**
Label: string (optional)
Label for a control. For example, a control representing a person's first name might have a label "First Name".
| Inherited from **ControlMetadata.Label** |

**LinkType**
LinkType: "Telephone" | "Email" | "Url" (optional)
Assigning the link type of a field allows for the appropriate mobile application to be opened when the link is selected.

**Mandatory**
Mandatory: boolean (optional)
If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.
| Inherited from **InputControlMetadata.Mandatory** |

**Name**
Name: string (optional)
Name of a control.
| Inherited from **ControlMetadata.Name** |

**NumSequence**
NumSequence: **NumberSequenceConfig** (optional)
Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```javascript
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
    referencePageName: 'numSeqReferencePage',
    dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```
**Order**

Order: number (optional)

Number indicating the order in which a control will appear on a page.

Inherited from `ControlMetadata.Order`

**ReferenceAppId**

ReferenceAppId: string (optional)

The ID of the app that the field control lives in.

**ReferencePageId**

ReferencePageId: string (optional)

The ID of the page that the field control lives in.

**Style**

Style: string (optional)

Styles a field of type "DateTime" or "Date". Example: `{ Style: TimeOnly }` result: 12:00:00 AM

**Type**

Type: `ControlType` (optional)

String indicating the control type.

Inherited from `ControlMetadata.Type`

**UnWrapText**

UnWrapText: boolean (optional)

False by default -- text of the page will be wrapped.

**WrapText**

WrapText: boolean (optional)

If true then the text of the field control will wrap to the next line.
File uploader control type. A control for uploading files such as images.

**Hierarchy**
- **Value**
  - FileUploader

**Index**

**Properties**
- container
- generic
- getDataSource
- hidden
- image

**Methods**
- applyDesign
- canLoadFromDevice
- dataContext
- getDesign
- getImage
- getValue
- isEditable
- loadFromFileSystem
- metadata
- parent
- root
- setCamera
- setValue

**Events**
- onDataChange

**Properties**

**container**
container: boolean (optional)
True if the control is a container.

Inherited from Control.container

**generic**
generic: boolean (optional)
getDataSource

getDataSource: function(): any

Inherited from Control.getDataSource

hidden

hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

image

image: Image

Methods

applyDesign

applyDesign(IDesign: FileUploaderDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDesign</td>
<td>FileUploaderDesign</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void
canLoadFromDevice
canLoadFromDevice(): boolean

Returns true if the mobile phone has camera plugin.

Returns boolean
dataContext
dataContext(): any

Inherited from Control.dataContext

Returns any
getDesign
getDesign(): Design

Returns the design object of this control.

Inherited from Control.getDesign
**getImage**

getImage(options: any): Promise <string>

Returns a promise of an object with image data.

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>any</td>
<td>see camera options</td>
</tr>
</tbody>
</table>

**getValue**

getValue(): any

Gets the value of the entity that is bound to the control.

Overrides Value.getValue

**isEditable**

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's editability and its parent's editability is undefined.

Inherited from Control.isEditable

**loadFromFileSystem**

loadFromFileSystem(file: Blob): Promise <any>

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>Blob</td>
<td></td>
</tr>
</tbody>
</table>

Returns Promise <any>

**metadata**

metadata(): FileUploaderMetadata

Returns the metadata object of this control.

Overrides Value.metadata

**parent**

parent(): Control | Page
Returns the parent (control or page) of this control.

<table>
<thead>
<tr>
<th>Returns</th>
<th>Control</th>
<th>Page</th>
</tr>
</thead>
</table>

**root**

root(): Page

Returns the root form instance (page) of this control.

<table>
<thead>
<tr>
<th>Returns</th>
<th>Control</th>
<th>Page</th>
</tr>
</thead>
</table>

**setCamera**

setCamera(camera: any): void

Set the camera object on the control.

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>camera</td>
<td>any</td>
<td></td>
</tr>
</tbody>
</table>

**Returns void**

**setValue**

setValue(value: string): void

Sets the value of the control.

<table>
<thead>
<tr>
<th>Returns</th>
<th>Control</th>
<th>Page</th>
</tr>
</thead>
</table>

**Events**

**onDataChanged**

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

<table>
<thead>
<tr>
<th>Returns</th>
<th>Control</th>
<th>Page</th>
</tr>
</thead>
</table>

Inherited from Control.parent

Inherited from Control.root

Inherited from Value.setValue

Inherited from InputControl.onDataChanged
File uploader design object type.

**Hierarchy**

ValueDesign

  ├── FileUploaderDesign

**Index**

**Properties**

- `alignItems`
- `alignSelf`
- `bindings`
- `border`
- `color`
- `flexFlow`
- `flexSize`
- `fontWeight`
- `justifyItems`
- `label`
- `labelPosition`
- `name`
- `padding`
- `type`

**Properties**

**alignItems**

`alignItems` is a string (optional)

This property is an alias for the CSS property "align-items". Please refer to [this web page](#) for documentation on the "align-items" property.

Inherited from Design.alignItems

**alignSelf**

`alignSelf` is a string (optional)

Inherited from Design.alignSelf

**bindings**

`bindings` is any (optional)

Inherited from Design.bindings
border
border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

Inherited from Design.border

color
color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute.
Note: if color is set to "theme", the theme color of the app will be used.

The following colors are available:

- blue: #0078D7
- pomegranate: #911844
- raspberry: #8D398F
- darkOrange: #D24726
- green: #369F47
- blueberry: #17234E
- grape: #432158
- lightBlue: #5DB2FF
- lightGreen: #82BA00
- pink: #DC4FAD
- teal: #008299
- mediumDarkBlue: #004B8B
- cordovan: #570000
- darkCordovan: #380000
- black: #000000
- lightGray: #e8e8e8
- light: #fff
- dark: #333333

Inherited from Design.color

flexFlow
flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

Inherited from Design.flexFlow

flexSize
flexSize: string (optional)
One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

| Inherited from Design.flexSize |

**fontSize**

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

| Inherited from Design.fontSize |

**fontWeight**

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

| Inherited from Design.fontSize |

**justifyItems**

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

| Inherited from Design.justifyItems |

**label**

label: string (optional)

| Inherited from Design.label |

**labelPosition**

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

| Inherited from Design.labelPosition |

**name**

name: string (optional)

| Inherited from Design.name |

**padding**

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

| Inherited from Design.padding |
**type**

*type: ControlType (optional)*

The type of the control as a string.

Inherited from `Design.type`
File uploader metadata type.

**Hierarchy**

ValueMetadata
  └ FileUploaderMetadata

**Index**

**Properties**

- **BoundEntity**
  BoundEntity: string (optional)

  The entity to which the control is bound.

  Inherited from ControlMetadata.BoundEntity

- **BoundField**
  BoundField: string (optional)

  Inherited from ControlMetadata.BoundField

- **Description**
  Description: string (optional)

  Description of the control.

  Inherited from ControlMetadata.Description
Editable
Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from ControlMetadataEditable

ExtType
ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from ControlMetadataExtType

HelpText
HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Inherited from ControlMetadataHelpText

Hidden
Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Inherited from ControlMetadataHidden

Id
Id: string (optional)

Identification string for a control.

Inherited from ControlMetadataId

Label
Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

Inherited from ControlMetadataLabel

Mandatory
Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

Inherited from InputControlMetadataMandatory

Name
Name: string (optional)
NumSequence

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```javascript
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
    referencePageName: 'numSeqReferencePage',
    dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

Type

Type: ControlType (optional)

String indicating the control type.
Generic value control type.

**Hierarchy**
- Value
  - GenericValue

**Index**

**Properties**
- container
- generic
- getDataSource
- hidden

**Methods**
- applyDesign
- dataContext
- getDesign

**Properties**

**container**
container: boolean (optional)

True if the control is a container.

Inherited from Control.container

**generic**
generic: boolean

True if the control is a generic.

Overrides Control.generic

**getDataSource**
**applyDesign**

applyDesign(design: Design): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Returns void

**dataContext**

dataContext(): any

Returns any

**getDesign**

getDesign(): Design

Returns the design object of this control.

Returns Design

**getValue**

getValue(): string

Returns the value of the control.

Returns string

**isEditable**

isEditable(): boolean
Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

| Inherited from | Control.isEditable |

**Returns boolean**

**metadata**

metadata(): `ValueMetadata`

Returns the metadata object of this control.

| Inherited from | Value.metadata |
| Inherited from | InputControl.metadata |

**Returns ValueMetadata**

**parent**

parent(): `Control` | `Page`

Returns the parent (control or page) of this control.

| Inherited from | Control.parent |

**Returns Control` | `Page**

**root**

root(): `Page`

Returns the root form instance (page) of this control.

| Inherited from | Control.root |

**Returns Page**

**setValue**

setValue(value: string): `void`

Sets the value of the control.

| Inherited from | Value.setValue |

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**Returns void**

**Events**

**onDataChanged**
onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

Inherited from InputControl.onDataChanged
Control interface with base methods and attributes for all controls. This represents the runtime instance of a control. Modifying the properties are immediately reflected in the UI.

### Properties

**container**

container: boolean (optional)

True if the control is a container.

**generic**

generic: boolean (optional)

**getDataSource**

gerDataSource: function(): any

**hidden**

hidden: boolean

True if the control is hidden.

### Methods
applyDesign
design: Design: void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>design</td>
<td>Design</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void
dataContext
dataContext(): any

Returns any
getDesign
getDesign(): Design

Returns the design object of this control.

Returns Design

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

Returns boolean

metadata

metadata(): ControlMetadata

Returns the metadata object of this control.

Returns ControlMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

Returns Page
Group container control type. A group control is a container control that has any number of controls as children.

Hierarchy

groupDataSource: function(): any
hidden
hidden: boolean
True if the control is hidden.

Methods

**applyDesign**

applyDesign(IDesign: GroupDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDesign</td>
<td>GroupDesign</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void

**dataContext**

dataContext(): any

Returns any

**getChildren**

getchildren(): Control []

Returns the list of children associated with this group control.

**getControl**

getchildren(controlName: string): Control

Given the name of a control, returns the control instance.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td>control name</td>
</tr>
</tbody>
</table>

Returns Control
getControlById(id: string): Control

Given the ID of a control, returns the control instance.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
<td>control ID</td>
</tr>
</tbody>
</table>

Returns Control
getchildren

getchildren(): Control

Returns the children of this control.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ContainerControl.getControlById</td>
<td></td>
</tr>
</tbody>
</table>

getDesign
getchildren

getchildren(): Design

Returns the design object of this control.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Control.getDesign</td>
<td></td>
</tr>
</tbody>
</table>

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

<table>
<thead>
<tr>
<th>Inherited from</th>

</tr>
</thead>
<tbody>
<tr>
<td>Control.isEditable</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns boolean</th>
<th></th>
</tr>
</thead>
</table>

metadata

metadata(): GroupMetadata

Returns the metadata object of this control.

<table>
<thead>
<tr>
<th>Overrides</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ContainerControl.metadata</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns GroupMetadata</th>
<th></th>
</tr>
</thead>
</table>

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Control.parent</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns Control</th>
<th>Page</th>
</tr>
</thead>
</table>

root

root(): Page

Returns the root form instance (page) of this control.
Inherited from `Control.root`

Returns `Page`
Group design object type.

**Hierarchy**

```
ContainerControlDesign
 └── GroupDesign
```

**Index**

**Properties**

- `alignItems`
- `alignSelf`
- `allowScroll`
- `background`
- `bindings`
- `border`
- `color`
- `flexFlow`
- `flexSize`
- `fontSize`
- `fontWeight`
- `itemBorder`
- `items`
- `justifyItems`
- `label`
- `labelPosition`
- `name`
- `padding`
- `type`

**Properties**

**alignItems**

`alignItems: string (optional)`

This property is an alias for the CSS property "align-items". Please refer to [this web page](#) for documentation on the "align-items" property.

Inherited from `Design.alignItems`

**alignSelf**

`alignSelf: string (optional)`

Inherited from `Design.alignSelf`
allowScroll
allowScroll: string (optional)

True if the container will allow scrolling when its items do not fit into the container’s available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.

| Inherited from | ContainerControlDesign.allowScroll |

background
background: string (optional)

The background color of the container. Consider modifying the color attribute in the same container so that fonts overlaying the background color will appear appropriately. Note: if background is set to “theme”, the theme color of the app will be used. The following colors are available:

- blue: #0078D7;
- pomegranate: #911844;
- raspberry: #8D398F;
- darkOrange: #D24726;
- green: #369F47;
- blueberry: #17234E;
- grape: #432158;
- lightBlue: #5DB2FF;
- lightGreen: #82BA00;
- pink: #DC4FAD;
- teal: #008299;
- mediumDarkBlue: #04B8B;
- cordovan: #570000;
- darkCordovan: #380000;
- black: #000000;
- lightGray: #e8e8e8;
- light: #fff;
- dark: #333333;

| Inherited from | ContainerControlDesign.background |

bindings
bindings: any (optional)

| Inherited from | Design.bindings |

border
border: “none” | “solid” | “left” | “right” | “top” | “bottom” (optional)

The border behavior of a control. This property will not be inherited by the children.

| Inherited from | Design.border |
**color**

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.

Consider setting the background color at the same time as necessary when setting this attribute.

Note: if color is set to "theme", the theme color of the app will be used.

The following colors are available:

- **blue**: #0078D7
- **pomegranate**: #911844
- **raspberry**: #8D398F
- **darkOrange**: #D24726
- **green**: #369F47
- **blueberry**: #17234E
- **grape**: #432158
- **lightBlue**: #5DB2FF
- **lightGreen**: #82BA00
- **pink**: #DC4FAD
- **teal**: #088299
- **mediumDarkBlue**: #004B8B
- **cordovan**: #570000
- **darkCordovan**: #380000
- **black**: #000000
- **lightGray**: #e8e8e8
- **light**: #fff
- **dark**: #333333

Inherited from Design.color

**flexFlow**

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

Inherited from Design.flexFlow

**flexSize**

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

Inherited from Design.flexSize

**fontSize**
The proportional text size

Inherited from Design.fontSize

**fontWeight**

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

Inherited from Design.fontWeight

**itemBorder**

itemBorder: "solid" | "none" (optional)

If true, a border will appear around each row in the list. This property is equivalent to applying the border property individually to all items in the container.

Inherited from ContainerControlDesign.itemBorder

**items**

items: string | Design [] (optional)

An array containing the components to place inside of the container.

Inherited from ContainerControlDesign.items

**justifyItems**

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

Inherited from Design.justifyItems

**label**

label: string (optional)

Inherited from Design.label

**labelPosition**

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

Inherited from Design.labelPosition

**name**

name: string (optional)

Inherited from Design.name

**padding**
**padding**: "none" | "small" | "std" (optional)

Allows specifying the component’s padding behavior. A component will inherit the padding behavior specified by its parent container components.

Inherited from `Design.padding`

---

**type**

type: `ControlType` (optional)

The type of the control as a string.

Inherited from `Design.type`
Group metadata type.

Hierarchy

- ContainerControlMetadata
  - GroupMetadata

Index

Properties

- **BoundEntity**
  BoundEntity: string (optional)

  The entity to which the control is bound.

  Inherited from ControlMetadata.BoundEntity

- **BoundField**
  BoundField: string (optional)

  Inherited from ControlMetadata.BoundField

- **Children**
  Children: ControlMetadata[] (optional)

  List of control metadata for each child control.

- **Description**
  Description: string (optional)
Description of the control.

**Editable**

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

Inherited from `ControlMetadataEditable`

**ExtType**

ExtType: `ControlType` (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from `ControlMetadataExtType`

**HelpText**

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Inherited from `ControlMetadataHelpText`

**Hidden**

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Inherited from `ControlMetadataHidden`

**Id**

Id: string (optional)

Identification string for a control.

Inherited from `ControlMetadataId`

**Label**

Label: string (optional)

Label for a control. For example, a control representing a person’s first name might have a label "First Name".

Inherited from `ControlMetadataLabel`

**Name**

Name: string (optional)

Name of a control.

Inherited from `ControlMetadataName`
### Order

**Order**: number (optional)

Number indicating the order in which a control will appear on a page.

Inherited from `ControlMetadata.Order`

### Type

**Type**: `ControlType` (optional)

String indicating the control type.

Inherited from `ControlMetadata.Type`
Hyperlink control type. Hyperlink control is a control to represent hyperlinks. Pagelinks can also be used in most cases.

container
container: boolean (optional)

True if the control is a container.

Inherited from Control.container

generic
generic: boolean (optional)

Inherited from Control.generic
**getDataSource**
getDataSource: function(): any

Inherited from Control.getDataSource

**hidden**
hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

**Methods**

**applyDesign**
applyDesign(IDesign: HyperLinkDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDesign</td>
<td>HyperLinkDesign</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void

**dataContext**
dataContext(): any

Inherited from Control.dataContext

Returns any

**getDesign**
getDesign(): Design

Returns the design object of this control.

Inherited from Control.getDesign

Returns Design

**getHyperLinkValue**
getHyperLinkValue(): string

Returns string

**getValue**
getValue(): string

Returns the value of the control.
Returns string

**isEditable**

**isEditable(): boolean**

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control’s editability and its parent’s editability is undefined.

Inherited from **Control.isEditable**

Returns boolean

**isHyperLinkURLPresent**

**isHyperLinkURLPresent(): boolean**

Returns boolean

**metadata**

**metadata(): HyperLinkMetadata**

Returns the metadata object of this control.

Overrides **Value.metadata**

Returns **HyperLinkMetadata**

**parent**

**parent(): Control | Page**

Returns the parent (control or page) of this control.

Inherited from **Control.parent**

Returns **Control | Page**

**root**

**root(): Page**

Returns the root form instance (page) of this control.

Inherited from **Control.root**

Returns **Page**

**setBaseURL**

**setBaseURL(url: string): any**

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**Returns any**
**setValue**

`setValue(value: string): void`

Sets the value of the control.

Inherited from `Value.setValue`

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
</tr>
<tr>
<td>value</td>
</tr>
</tbody>
</table>

**Returns void**

**Events**

**onDataChanged**

`onDataChanged: EventHook <null>`

An event that is triggered when the input control's data changes.

Inherited from `InputControl.onDataChanged`
Hyperlink design object type.

- justifyItems
- label
- labelPosition
- name
- padding
- type

Properties

alignItems

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

| Inherited from Design.alignItems |

alignSelf

alignSelf: string (optional)

| Inherited from Design.alignSelf |

bindings

bindings: any (optional)

| Inherited from Design.bindings |
border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

| Inherited from Design.border |

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.

Consider setting the background color at the same time as necessary when setting this attribute.

Note: if color is set to "theme", the theme color of the app will be used.

The following colors are available:

- **blue**: #0078D7
- **pomegranate**: #911844
- **raspberry**: #8D398F
- **darkOrange**: #D24726
- **green**: #369F47
- **blueberry**: #17234E
- **grape**: #432158
- **lightBlue**: #5DB2FF
- **lightGreen**: #82BA00
- **pink**: #DC4FAD
- **teal**: #008299
- **mediumDarkBlue**: #004B8B
- **cordovan**: #570000
- **darkCordovan**: #380000
- **black**: #000000
- **lightGray**: #E8E8E8
- **light**: #FFF
- **dark**: #333333

| Inherited from Design.color |

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

| Inherited from Design.flexFlow |

flexSize

flexSize: string (optional)
One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

- **fontSize**
  
  fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)
  
  The proportional text size

- **fontWeight**
  
  fontWeight: "normal" | "bold" (optional)
  
  Normal or bold text.

- **justifyItems**
  
  justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)
  
  This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

- **label**
  
  label: string (optional)

- **labelPosition**
  
  labelPosition: "stacked" | "hidden" | "inline" (optional)
  
  Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

- **name**
  
  name: string (optional)

- **padding**
  
  padding: "none" | "small" | "std" (optional)
  
  Allows specifying the component’s padding behavior. A component will inherit the padding behavior specified by its parent container components.
**type**

Type: `ControlType` (optional)

The type of the control as a string.

Inherited from `Design.type`
Hyperlink metadata type.

**Hierarchy**

ValueMetadata
  └ HyperLinkMetadata

**Index**

**Properties**

- **BoundEntity**
  - `BoundEntity` string (optional)
  
  The entity to which the control is bound.

  Inherited from `ControlMetadata.BoundEntity`

- **BoundField**
  - `BoundField` string (optional)

  Inherited from `ControlMetadata.BoundField`

- **Description**
  - `Description` string (optional)

  Description of the control.

  Inherited from `ControlMetadata.Description`
**Editable**
Editable: boolean (optional)
Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

Inherited from `ControlMetadataEditable`

**ExtType**
ExtType: `ControlType` (optional)
The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from `ControlMetadataExtType`

**HelpText**
HelpText: string (optional)
The keyboard shortcut for a command. For example, "(Shift+F5)"

Inherited from `ControlMetadataHelpText`

**Hidden**
Hidden: boolean (optional)
Boolean indicating if the control is hidden or not.

Inherited from `ControlMetadataHidden`

**Id**
Id: string (optional)
Identification string for a control.

Inherited from `ControlMetadataId`

**Label**
Label: string (optional)
Label for a control. For example, a control representing a person's first name might have a label "First Name".

Inherited from `ControlMetadataLabel`

**Mandatory**
Mandatory: boolean (optional)
If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

Inherited from `InputControlMetadataMandatory`

**Name**
Name: string (optional)
### Name of a control.

| Inherited from | [ControlMetadata.Name](#) |

---

### NumSequence

**NumSequence**: `NumberSequenceConfig` (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```javascript
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
  referencePageName: 'numSeqReferencePage',
  dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

| Inherited from | [InputControlMetadata.NumSequence](#) |

---

### Order

**Order**: number (optional)

Number indicating the order in which a control will appear on a page.

| Inherited from | [ControlMetadata.Order](#) |

---

### Type

**Type**: `ControlType` (optional)

String indicating the control type.

| Inherited from | [ControlMetadata.Type](#) |
Image control interface for representing images in the mobile app. Images can be of any of the following types: DataUri, Base64, URL, AOTResource, or Symbol.

**Hierarchy**

Control
  └— Image

**Properties**

**container**

container: boolean (optional)

True if the control is a container.

Inherited from Control.container

**generic**

generic: boolean (optional)

Inherited from Control.generic

**getDataSource**

getAddress: function(): any
hidden
hidden: boolean
True if the control is hidden.

imageSource
imageSource: string
Defines the imageSource.

imageView
imageView: string
Dictates the style of the image.

placeholderClass
placeholderClass: string

symbol
symbol: string
Defines the symbol if the image is of type symbol.

Methods

applyDesign
applyDesign(design: ImageDesign): void
Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>design</td>
<td>ImageDesign</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void
dataContext
dataContext(): any

Inherited from Control.dataContext

Returns any
getDesign
getDesign(): Design

Returns the design object of this control.
isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control’s editability and its parent’s editability is undefined.

metadata(): ImageMetadata

Returns the metadata object of this control.

parent(): Control | Page

Returns the parent (control or page) of this control.

root(): Page

Returns the root form instance (page) of this control.
Image design object type.

**Hierarchy**

- Design
  - ImageDesign

- darkCordovan: #380000
- black: #000000
- lightGray: #e8e8e8
- light: #fff
- dark: #333333

Inherited from Design.color

**flexFlow**

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

Inherited from Design.flexFlow
**flexSize**

flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

Inherited from Design.flexSize

**fontSize**

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

Inherited from Design.fontSize

**fontWeight**

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

Inherited from Design.fontWeight

**height**

height: string (optional)

The relative vertical size of the image. Sizes are about equivalent to CSS em sizes.

**imageStyle**

imageStyle: ImageStyleType (optional)

The style of the image.

**justifyItems**

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

Inherited from Design.justifyItems

**label**

label: string (optional)

Inherited from Design.label

**labelPosition**

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

Inherited from Design.labelPosition

**name**
name: string (optional)

Inherited from Design.name

**padding**

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

Inherited from Design.padding

**type**

type: ControlType (optional)

The type of the control as a string.

Inherited from Design.type

**width**

width: string (optional)

The relative horizontal size of the image. Sizes are about equivalent to CSS em sizes.
Image metadata type.

**Hierarchy**

ControlMetadata

  └ ImageMetadata

**Index**

**Properties**

- **BaseUrl**
  
  BaseUrl: string (optional)

  Base URL for AOTResource type image.

- **BoundEntity**
  
  BoundEntity: string (optional)

  The entity to which the control is bound.

  Inherited from ControlMetadata.BoundEntity

- **BoundField**
  
  BoundField: string (optional)

  Inherited from ControlMetadata.BoundField
**Description**
Description: string (optional)
Description of the control.

Inherited from ControlMetadata.Description

**Editable**
Editable: boolean (optional)
Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from ControlMetadata.Edible

**ExtType**
ExtType: ControlType (optional)
The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from ControlMetadata.ExtType

**Height**
Height: number (optional)
The relative vertical size of the image. Sizes are about equivalent to CSS em sizes.

**HelpText**
HelpText: string (optional)
The keyboard shortcut for a command. For example, "(Shift+F5)"

Inherited from ControlMetadata.HelpText

**Hidden**
Hidden: boolean (optional)
Boolean indicating if the control is hidden or not.

Inherited from ControlMetadata.Hidden

**Id**
Id: string (optional)
Identification string for a control.

Inherited from ControlMetadata.Id

**ImageStyle**
ImageStyle: ImageStyleType (optional)
The style of the image.

**Label**
Label: string (optional)
Label for a control. For example, a control representing a person's first name might have a label "First Name".

| Inherited from ControlMetadata.Label |

Name
Name: string (optional)
Name of a control.

| Inherited from ControlMetadata.Name |

Order
Order: number (optional)
Number indicating the order in which a control will appear on a page.

| Inherited from ControlMetadata.Order |

Type
Type: ControlType (optional)
String indicating the control type.

| Inherited from ControlMetadata.Type |

Width
Width: number (optional)
The relative horizontal size of the image. Sizes are about equivalent to CSS em sizes.
Input control interface with methods and attributes for all input controls. Input controls are typically used on task pages for collecting user input, for example, for a new control.

**generic**
generic: boolean (optional)

| Inherited from | Control.generic |
**getDataSource**

getDataSource: function(): any

Inherited from Control.getDataSource

**hidden**

hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

## Methods

### applyDesign

applyDesign(design: Design): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Inherited from Control.applyDesign

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>design</td>
<td>Design</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void

### dataContext

dataContext(): any

Inherited from Control.dataContext

Returns any

### getDesign

getDesign(): Design

Returns the design object of this control.

Inherited from Control.getDesign

Returns Design

### isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from Control.isEditable
Returns boolean

metadata

metadata(): InputControlMetadata

Returns the metadata object of this control.

| Overrides Control.metadata |

Returns InputControlMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

| Inherited from Control.parent |

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

| Inherited from Control.root |

Returns Page

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.
Input control design.

- dark: 🔊 #333333;

| Inherited from Design.color |

**flexFlow**

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.
Inherited from Design.flexFlow

**flexSize**

`flexSize: string (optional)`

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

Inherited from Design.flexSize

**fontSize**

`fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)`

The proportional text size

Inherited from Design.fontSize

**fontWeight**

`fontWeight: "normal" | "bold" (optional)`

Normal or bold text.

Inherited from Design.fontWeight

**justifyItems**

`justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)`

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

Inherited from Design.justifyItems

**label**

`label: string (optional)`

Inherited from Design.label

**labelPosition**

`labelPosition: "stacked" | "hidden" | "inline" (optional)`

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

Inherited from Design.labelPosition

**name**

`name: string (optional)`

Inherited from Design.name

**padding**

`padding: "none" | "small" | "std" (optional)"
Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

| Inherited from Design.padding |

**type**

Type: `ControlType` (optional)

The type of the control as a string.

| Inherited from Design.type |
Metadata for input controls.

- **ExtType**
- **HelpText**
- **Hidden**
- **Id**
- **Label**
- **Mandatory**
- **Name**
- **NumSequence**
- **Order**
- **Type**

**Properties**

**BoundEntity**

BoundEntity: string (optional)

The entity to which the control is bound.

Inherited from ControlMetadata.BoundEntity

**BoundField**

BoundField: string (optional)

Inherited from ControlMetadata.BoundField

**Description**

Description: string (optional)
Description of the control.

| Inherited from ControlMetadata.Description |

**Editable**

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

| Inherited from ControlMetadata.Editable |

**ExtType**

ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

| Inherited from ControlMetadata.ExtType |

**HelpText**

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

| Inherited from ControlMetadata.HelpText |

**Hidden**

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

| Inherited from ControlMetadata.Hidden |

**Id**

Id: string (optional)

Identification string for a control.

| Inherited from ControlMetadata.Id |

**Label**

Label: string (optional)

Label for a control. For example, a control representing a person’s first name might have a label "First Name".

| Inherited from ControlMetadata.Label |

**Mandatory**

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.
Name
Name: string (optional)

Name of a control.

   Inherited from ControlMetadata.Name

NumSequence
NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```javascript
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
    referencePageName: 'numSeqReferencePage',
    dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

Order
Order: number (optional)

Number indicating the order in which a control will appear on a page.

   Inherited from ControlMetadata.Order

Type
Type: ControlType (optional)

String indicating the control type.

   Inherited from ControlMetadata.Type
List control type. A list is a control that contains any numbers of rows. Each row follows a template for the layout of any number of controls. Lists come in two styles: simple and card.

**Properties**

$accessibility
$accessibility: any

**DefaultSearchColumn**
DefaultSearchColumn: string

**container**
container: boolean
True if the control is a container.

- Inherited from `ContainerControl.container`
- Overrides `Control.container`

**emptyListMessage**
emptyListMessage: string
Settable property to override default empty list message.

**enableMultiSelect**
enableMultiSelect: boolean

**generic**
generic: boolean (optional)

- Inherited from `Control.generic`

**getDataSource**
getDataSource: function(): any

- Inherited from `Control.getDataSource`
**hidden**

hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

**hideEmptyListMessage**

hideEmptyListMessage: boolean

If true, no message is shown if the list is empty. To set this property, update the corresponding metadata property via configureControl.

**imageFields**

imageFields: any []

**performingRemoteSearch**

performingRemoteSearch: boolean

**searchQuery**

searchQuery: [value: string]: any

### Methods

**allowsNavigation**

allowsNavigation(): boolean

**applyDesign**

applyDesign(IDesign: ListDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDesign</td>
<td>ListDesign</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

**applySearch**

applySearch(): void

**canPerformRemoteSearch**

canPerformRemoteSearch(): boolean

**clearSearch**

clearSearch(): void
**Returns void**

dataContext
dataContext(): any

Inherited from `Control.dataContext`

**Returns any**

getColumnLabel
getColumnLabel(id: string): string

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**Returns string**

getControl
getControl(controlName: string): `Control`

Given the name of a control, returns the control instance.

Inherited from `ContainerControl.getControl`

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td>control name</td>
</tr>
</tbody>
</table>

**Returns `Control`**

getControlById
getControlById(id: string): `Control`

Given the ID of a control, returns the control instance.

Inherited from `ContainerControl.getControlById`

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
<td>control ID</td>
</tr>
</tbody>
</table>

**Returns `Control`**

getControlMetadata
getControlMetadata(controlName: string): `Control`

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>
getControlMetadataById

getControlMetadataById(id: string): Control

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

Returns Control

data

data(): any []

Returns any []

design

design(): Design

Returns the design object of this control.

Inherited from Control.getDesign

Returns Design

getListData

getListData(): any

Returns any

getRenderedRows

getRenderedRows(): Row []

Returns Row []

getRowNavigation

getRowNavigation(row: Row): Promise <any> | any

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Row</td>
<td></td>
</tr>
</tbody>
</table>

Returns Promise <any> | any

getRowSelectionCount

getRowSelectionCount(): number

Returns number

getRowSelections

getRowSelections(): string []

Returns string []

getRowTracking

getRowTracking(row: any, index: string): string

Parameters
<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>any</td>
<td>Returns string</td>
</tr>
<tr>
<td>index</td>
<td>string</td>
<td>Returns string</td>
</tr>
</tbody>
</table>

**getSearchColumn**

getSearchColumn(): string

Returns string

**getSearchColumnLabel**

getSearchColumnLabel(): string

Returns string

**getSearchableColumns**

getSearchableColumns(): any [ ]

Returns any [ ]

**hideSearchBar**

hideSearchBar(): boolean

Returns boolean

**isEditable**

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from Control.isEditable

**loadMetaData**

loadMetaData(): void

Returns void

**loadMore**

loadMore(): void

Returns void

**metadata**

metadata(): ListMetadata

Returns the metadata object of this control.

Overrides ContainerControl.metadata

Returns ListMetadata

**parent**
parent(): Control | Page

Returns the parent (control or page) of this control.

Inherited from Control.parent

performRemoteSearch(): void

Returns Control | Page

root(): Page

Returns the root form instance (page) of this control.

Inherited from Control.root

selectSearchColumn(column: string): void

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

Returns void

setRowSections(selections: string [ ]): void

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>selections</td>
<td>string [ ]</td>
<td></td>
</tr>
</tbody>
</table>

Returns void

Events

onRowCreate: EventHook <Row>

onRowSelect: EventHook <Row>
List design object type.

### Hierarchy

ContainerControlDesign  
  └ ListDesign

### Index

#### Properties

- `alignItems`
- `alignSelf`
- `allowScroll`
- `background`
- `bindings`
- `border`
- `color`
- `design`
- `flexFlow`
- `flexSize`
- `fontSize`
- `fontWeight`
- `hideArrow`
- `hideSearchBar`
- `itemBorder`
- `items`
- `justifyItems`
- `label`
- `labelPosition`
- `name`
- `padding`
- `type`

#### Properties

**alignItems**  
`alignItems: string (optional)`

This property is an alias for the CSS property "align-items". Please refer to [this web page](#) for documentation on the "align-items" property.

Inherited from Design.alignItems
alignSelf: string (optional)

| Inherited from Design.alignSelf |

allowScroll

allowScroll: string (optional)

True if the container will allow scrolling when its items do not fit into the container's available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.

| Inherited from ContainerControlDesign.allowScroll |

background

background: string (optional)

The background color of the container. Consider modifying the color attribute in the same container so that fonts overlaying the background color will appear appropriately. Note: if background is set to "theme", the theme color of the app will be used. The following colors are available:

- **blue**: #0078D7
- **pomegranate**: #911844
- **raspberry**: #8D398F
- **darkOrange**: #D24726
- **green**: #369F47
- **blueberry**: #17234E
- **grape**: #432158
- **lightBlue**: #5DB2FF
- **lightGreen**: #82BA00
- **pink**: #DC4FAD
- **teal**: #008299
- **mediumDarkBlue**: #004B8B
- **cordovan**: #570000
- **darkCordovan**: #380000
- **black**: #000000
- **lightGray**: #e8e8e8
- **light**: #fff
- **dark**: #333333

| Inherited from ContainerControlDesign.background |

bindings

bindings: any (optional)

| Inherited from Design.bindings |

border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)
The border behavior of a control. This property will not be inherited by the children.

| Inherited from Design.border |

**color**
color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container. Consider setting the background color at the same time as necessary when setting this attribute. Note: if color is set to "theme", the theme color of the app will be used.

The following colors are available:

- **blue**: #0078D7
- **pomegranate**: #911844
- **raspberry**: #B03060
- **darkOrange**: #D24726
- **green**: #369F47
- **blueberry**: #17238E
- **grape**: #432158
- **lightBlue**: #6DB2FF
- **lightGreen**: #82BA00
- **pink**: #DC4FAD
- **teal**: #008299
- **mediumDarkBlue**: #004B8B
- **cordovan**: #570000
- **darkCordovan**: #380000
- **black**: #000000
- **lightGray**: #e8e8e8
- **light**: #fff
- **dark**: #333333

| Inherited from Design.color |

**design**
design: GroupDesign (optional)

The design object that will be applied to each row.

**flexFlow**
flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

| Inherited from Design.flexFlow |

**flexSize**
flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

| Inherited from Design.flexSize |

**fontSize**

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

| Inherited from Design.fontSize |

**fontWeight**

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

| Inherited from Design.fontWeight |

**hideArrow**

hideArrow: boolean (optional)

Allows an arrow ( > ) on a default styled navigation control to be hidden. Note that if the list has DetailsPageld, navigationHandler, or OnNavigate in the metadata then by default the arrows are present in each row of the list to show that the rows are clickable.

This property can only be added through the design object.

**hideSearchBar**

hideSearchBar: boolean (optional)

If true, the search bar will be hidden.

**itemBorder**

itemBorder: "solid" | "none" (optional)

If true, a border will appear around each row in the list. This property is equivalent to applying the border property individually to all items in the container.

| Inherited from ContainerControlDesign.itemBorder |

**items**

items: string | Design [ ] (optional)

An array containing the components to place inside of the container.

| Inherited from ContainerControlDesign.items |

**justifyItems**

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation...
on the "justify-content" property.

- label
  label: string (optional)
  Inherited from Design.label

- labelPosition
  labelPosition: "stacked" | "hidden" | "inline" (optional)
  Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.
  Inherited from Design.labelPosition

- name
  name: string (optional)
  Inherited from Design.name

- padding
  padding: "none" | "small" | "std" (optional)
  Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.
  Inherited from Design.padding

- type
  type: ControlType (optional)
  The type of the control as a string.
  Inherited from Design.type
Metadata for list control.

<tr>
<td><strong>HelpText</strong></td>
<td><strong>HelpText</strong>: string (optional)</td>
</tr>
</tbody>
</table>
The keyboard shortcut for a command. For example, "(Shift+F5)"

| Inherited from ControlMetadata.HelpText |

**Hidden**

Hidden boolean (optional)

Boolean indicating if the control is hidden or not.

| Inherited from ControlMetadata.Hidden |

**HideEmptyListMessage**

HideEmptyListMessage boolean (optional)

If true, the empty list message will be hidden.

**HideSearchBar**

HideSearchBar boolean (optional)

If true, the search bar will be hidden.

**Id**

Id string (optional)

Identification string for a control.

| Inherited from ControlMetadata.Id |

**InfiniteScroll**

InfiniteScroll boolean (optional)

If set to true then the list will allow infinite scroll.

**InfiniteScrollPageSize**

InfiniteScrollPageSize number (optional)

Number of rows to load initially and the number of rows to load after the user reaches the end of the currently displayed rows.

**Label**

Label string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

| Inherited from ControlMetadata.Label |

**ListStyle**

ListStyle string (optional)

Dictates the list template type. Options:

- "Simple": simple style
- "Card": card style

**MultiSelect**

MultiSelect boolean (optional)

If true, then the list will be a multi-select list.

**Name**

Name: string (optional)

Name of a control.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>ControlMetadata.Name</th>
</tr>
</thead>
</table>

**NonEntityProjection**

NonEntityProjection: boolean (optional)

**Order**

Order: number (optional)

Number indicating the order in which a control will appear on a page.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>ControlMetadata.Order</th>
</tr>
</thead>
</table>

**Type**

Type: ControlType (optional)

String indicating the control type.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>ControlMetadata.Type</th>
</tr>
</thead>
</table>

**Methods**

**navigationHandler**

Optional

navigationHandler(row: Row): Promise <any> | NavigationArgs

A function that determines the navigation for a given row.

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>Row</td>
<td>row to get navigation handler for.</td>
</tr>
</tbody>
</table>

| Returns | Promise <any> | NavigationArgs |

**Events**

**OnNavigate**

An event that is triggered when a pagelink control is selected.

**OnRowSelect**

OnRowSelect: function(row: Row): void (optional)

An event that is triggered when a row is selected.
Lookup control type. A lookup is an input control that is used to select an input from a list of options. For example, a lookup could be used to lookup a customer when linking a customer to a new sales order.

**Hierarchy**

```
InputControl
  └ Lookup
```

**Index**

**Properties**

- `getLookupPage`
- `getValue`
- `isEditable`
- `metadata`
- `parent`
- `root`
- `setEntityRef`

**Events**
- `onDataChanged`

**Properties**

**container**

container: boolean (optional)

True if the control is a container.

Inherited from `Control.container`

**generic**

generic: boolean (optional)

Inherited from `Control.generic`
**getDataSource**
getDataSource: function(): any

Inherited from Control.getDataSource

**hidden**
hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

**Methods**

**applyDesign**
applyDesign(IDesign: LookupDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDesign</td>
<td>LookupDesign</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void

**dataContext**

dataContext(): any

Inherited from Control.dataContext

Returns any

**getDesign**

getDesign(): Design

Returns the design object of this control.

Inherited from Control.getDesign

Returns Design

**getDisplayValue**

getDisplayValue(): string

Returns string

**getLookupPage**

getLookupPage(): Page

Returns Page

**getValue**
getValue(): string | number

Returns string | number

isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from Control.isEditable

Returns boolean

metadata

metadata(): LookupMetadata

Returns the metadata object of this control.

Overrides InputControl.metadata

Returns LookupMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

Inherited from Control.root

Returns Page

setEntityRef

setEntityRef(newValue: string | number): Promise <any>

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>newValue</td>
<td>string</td>
<td>number</td>
</tr>
</tbody>
</table>

Returns Promise <any>

Events

onDataChanged
onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

Inherited from InputControl.onDataChanged
Lookup design object type.

Hierarchy
InputControlDesign
  └ LookupDesign

Properties
- alignItems
- alignSelf
- bindings
- border
- color
- flexGrow
- flexSize
- fontWeight
- justifyItems
- label
- labelPosition
- name
- padding
- type

Properties

alignItems
alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

Inherited from Design.alignItems

alignSelf
alignSelf: string (optional)

Inherited from Design.alignSelf

bindings
bindings: any (optional)

Inherited from Design.bindings
**border**

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

Inherited from Design.border

**color**

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.

Consider setting the background color at the same time as necessary when setting this attribute.

Note: if color is set to "theme", the theme color of the app will be used.

The following colors are available:

- **blue**: #0078D7;
- **pomegranate**: #911844;
- **raspberry**: #8D398F;
- **darkOrange**: #D24726;
- **green**: #369F47;
- **blueberry**: #1723E;
- **grape**: #432158;
- **lightBlue**: #5DB2FF;
- **lightGreen**: #82BA00;
- **pink**: #DC4FAD;
- **teal**: #008299;
- **mediumDarkBlue**: #04B8B;
- **cordovan**: #570000;
- **darkCordovan**: #380000;
- **black**: #000000;
- **lightGray**: #8e8e8e;
- **light**: #fff;
- **dark**: #333333;

Inherited from Design.color

**flexFlow**

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

Inherited from Design.flexFlow

**flexSize**

flexSize: string (optional)
One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to [this web page](#) for documentation on the "flex" property.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>Design.flexSize</th>
</tr>
</thead>
</table>

**fontSize**

`font-size: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)`

The proportional text size

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>Design.fontSize</th>
</tr>
</thead>
</table>

**fontWeight**

`font-weight: "normal" | "bold" (optional)`

Normal or bold text.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>Design.fontWeight</th>
</tr>
</thead>
</table>

**justifyItems**

`justify-items: "flex-start" | "flex-end" | "center" | "space-between" (optional)`

This property is an alias for the CSS property "justify-content". Please refer to [this web page](#) for documentation on the "justify-content" property.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>Design.justifyItems</th>
</tr>
</thead>
</table>

**label**

`label: string (optional)`

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>Design.label</th>
</tr>
</thead>
</table>

**labelPosition**

`label-position: "stacked" | "hidden" | "inline" (optional)`

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>Design.labelPosition</th>
</tr>
</thead>
</table>

**name**

`name: string (optional)`

<table>
<thead>
<tr>
<th>Inherited from</th>
<th>Design.name</th>
</tr>
</thead>
</table>

**padding**

`padding: "none" | "small" | "std" (optional)`

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

<table>
<thead>
<tr>
<th>Inherited from</th>

Properties

BoundEntity
BoundEntity: string (optional)
The entity to which the control is bound.

Inherited from `ControlMetadata.BoundEntity`

**BoundField**

BoundField: string (optional)

Inherited from `ControlMetadata.BoundField`

**Description**

Description: string (optional)

Description of the control.

Inherited from `ControlMetadata.Description`

**DisplayField**

DisplayField: string (optional)

The name of a control on the page, whose value should be displayed to the user. Usually, this value is user-friendly/user-readable text.

**DisplayKey**

DisplayKey: string (optional)

**Editable**

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

Inherited from `ControlMetadata.Editable`

**ExtType**

ExtType: `ControlType` (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from `ControlMetadata.ExtType`

**FilterContext**

FilterContext: DataFilter (optional)

**HelpText**

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Inherited from `ControlMetadata.HelpText`

**Hidden**

Hidden: boolean (optional)
Boolean indicating if the control is hidden or not.

| Inherited from ControlMetadata.Hidden |

**Id**

Id: string (optional)

Identification string for a control.

| Inherited from ControlMetadata.Id |

**Label**

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

| Inherited from ControlMetadata.Label |

**LookupEntity**

LookupEntity: any (optional)

The entity that is being looked up in the lookup.

**LookupPage**

LookupPage: string (optional)

**LookupPageId**

LookupPageId: string (optional)

**Mandatory**

Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

| Inherited from InputControlMetadata.Mandatory |

**MultiSelect**

MultiSelect: boolean (optional)

If true, lookup will be configured as a multi-select.

**Name**

Name: string (optional)

Name of a control.

| Inherited from ControlMetadata.Name |

**NumSequence**

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
    referencePageName: 'numSeqReferencePage',
    dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });

Inherited from InputControlMetadata.NumSequence

Order

Order: number (optional)

Number indicating the order in which a control will appear on a page.

Inherited from ControlMetadata.Order

ReferenceAppId

ReferenceAppId: string (optional)

ShowLookupPage

ShowLookupPage: boolean (optional)

Type

Type: ControlType (optional)

String indicating the control type.

Inherited from ControlMetadata.Type

ValueField

ValueField: string (optional)

The name of a control on the page, whose value should be used when committing the data. Usually, this value is a unique key.

ValueKey

ValueKey: string (optional)

Events

OnOptionSelected

OnOptionSelected: function(lookup: any, lookupEntityData: any): void (optional)

An event that is triggered by an option being selected.

OnValueChanged

OnValueChanged: function(value: any): void (optional)

An event that is triggered by a value being changed.
Provides ability to access and configure various metadata elements under the application workspace.

**Hierarchy**
MetadataService

**Index**

**Properties**

- **version**

**Methods**

- **addControl**
- **compareVersion**
- **configureAction**
- **configureControl**
- **configureEntity**
- **configureLookup**
- **configurePage**
- **configureWorkspace**
- **findAction**
- **findControl**
- **findPage**
- **getFilterExpression**
- **getFormReference**
- **hideNavigation**

**Properties**

**version**

version: string

(Read-only) Gets the version of the platform currently running.

**Methods**

**addControl**

addControl(componentName: string, controlName: string, controlType: ControlType, parentContainerName?: string, options?: ControlMetadata): any

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>componentName</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>NAME</td>
<td>TYPE</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlName</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>controlType</td>
<td>ControlType</td>
<td></td>
</tr>
<tr>
<td>parentContainerName?</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>options?</td>
<td>ControlMetadata</td>
<td></td>
</tr>
</tbody>
</table>

**compareVersion**

 Returns any

`compareVersion(versionToCompare: string): 1 | -1`

Compares the current platform version with a reference version.

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>versionToCompare</td>
<td>string</td>
<td>The reference version to compare with</td>
</tr>
</tbody>
</table>

**Returns 1 | -1**

1 to indicate the platform version is older than the reference version, -1 to indicate that the platform version is newer or same as the reference version

**configureAction**

`configureAction(actionName: string, options: PageMetadata): any`

Configuring an action allows specifying or overriding certain behaviors specific to actions. Example:

```
metadataService.configureAction('Edit-Reservation', { properties-to-set });
```

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionName</td>
<td>string</td>
<td>The action whose behavior is to be changed</td>
</tr>
<tr>
<td>options</td>
<td>PageMetadata</td>
<td>The property bag containing the properties to set on the action</td>
</tr>
</tbody>
</table>

**Returns any**

**configureControl**

`configureControl(componentName: string, controlName: string, options: ControlMetadata): any`

Configuring a control allows specifying or overriding certain behaviors specific to the control. Note that the available behaviors vary by control type. Example:

```
metadataService.configureControl('All-Customers', 'FMCustomer_RecId', { properties-to-set });
```

**Parameters**
<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>componentName</td>
<td>string</td>
<td>A page or action that contains the control</td>
</tr>
<tr>
<td>controlName</td>
<td>string</td>
<td>The control whose behavior is to be changed</td>
</tr>
<tr>
<td>options</td>
<td>ControlMetadata</td>
<td>The property bag containing the properties to set on the control</td>
</tr>
</tbody>
</table>

Returns any

**configureEntity**
configureEntity(entityName: string, options: any): any

Configuring an entity allows specifying or overriding certain behaviors specific to the entity. Example:

```javascript
metadataService.configureEntity("FMCustomer", { properties-to-set });
```

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>entityName</td>
<td>string</td>
<td>An entity name</td>
</tr>
<tr>
<td>options</td>
<td>any</td>
<td>The property bag containing the properties to set on the entity</td>
</tr>
</tbody>
</table>

Returns any

**configureLookup**
configureLookup(taskName: string, lookupControlName: string, options: LookupMetadata): any

Configures a field on an action to behave as a lookup. Requires using an existing page which contains a list control. Example:

```javascript
metadataService.configureLookup('Add-Reservation', 'FMRental_Customer', { lookupPage: 'All-Customers', valueField: 'FMCustomer_RecId', displayField: 'FMCustomer_FullName'});
```

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>taskName</td>
<td>string</td>
<td>Action name</td>
</tr>
<tr>
<td>lookupControlName</td>
<td>string</td>
<td>The control name of the field to be given lookup behavior</td>
</tr>
<tr>
<td>options</td>
<td>LookupMetadata</td>
<td>Lookup configuration object</td>
</tr>
</tbody>
</table>

Returns any

**configurePage**
configurePage(pageName: string, options: PageMetadata): any

Configuring a Page allows specifying or overriding certain behaviors specific to the Page. Example:
metadataService.configurePage('Reservation-details', { properties-to-set });

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageName</td>
<td>string</td>
<td>The page that contains the control</td>
</tr>
<tr>
<td>options</td>
<td>PageMetadata</td>
<td>The property bag containing the properties to set on the page</td>
</tr>
</tbody>
</table>

**Returns any**

**configureWorkspace**

configureWorkspace(options: PageMetadata): any

Configuring a workspace allows specifying or overriding certain behaviors specific to the workspace. Example:

```javascript
metadataService.configureWorkspace({ properties-to-set });
```

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>PageMetadata</td>
<td>The property bag containing the properties to set on the workspace</td>
</tr>
</tbody>
</table>

**Returns any**

**findAction**

findAction(actionName: string): PageMetadata

Gets a copy of the current metadata instance of a specified Action, for the purpose of inspecting the metadata (not to be used for changing the metadata). Note: Since metadata can be changed at any time by business logic, you must be mindful of when you use this API to get a copy as it will reflect the state of the metadata at the time the call is made.

Example:

```javascript
var newCustomerTaskMetadata = metadataService.findTask("New-customer");
```

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionName</td>
<td>string</td>
<td>An action name</td>
</tr>
</tbody>
</table>

**Returns** PageMetadata

**findControl**

findControl(componentMetadata: any, controlName: string): ControlMetadata

Gets a copy of the current metadata instance of a specified control, for the purpose of inspecting the metadata (not to be used for changing the metadata). Note: Since metadata can be changed at any time by business logic, you must be mindful of when you use this API to get a copy as it will reflect the state of the metadata at the time the call is made.
Example:

```javascript
var firstNameControl = metadataService.findControl(newCustomerTaskMetadata, 'FMCustomer_FirstName');
```

<table>
<thead>
<tr>
<th>Parameters</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>componentMetadata</td>
<td>any</td>
<td>A metadata instance of the page or action</td>
</tr>
<tr>
<td>controlName</td>
<td>string</td>
<td>A control name</td>
</tr>
</tbody>
</table>

**Returns** [ControlMetadata](#)

### findPage

**findPage**(pageName: string): [PageMetadata](#)

Gets a copy of the current metadata instance of a specified page, for the purpose of inspecting the metadata (not to be used for changing the metadata). Note: Since metadata can be changed at any time by business logic, you must be mindful of when you use this API to get a copy as it will reflect the state of the metadata at the time the call is made.

Example:

```javascript
var reservationDetailsMetadata = metadataService.findPage("Reservation-details");
```

<table>
<thead>
<tr>
<th>Parameters</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageName</td>
<td>string</td>
<td>A page name</td>
</tr>
</tbody>
</table>

**Returns** [PageMetadata](#)

### getFilterExpression

**getFilterExpression**(pageName: string, listControlName: string, controlName: string, operator: [ExpressionOperator](#), value: string): DataFilter

Create a DataFilter object for a list control based on the provided options. Example:

```javascript
var filter = metadataService.getFilterExpression(
    pageNames.AllCustomers, controlNames.Customerlist, controlNames.CustomerFullName, "Is", firstCustomerName),
```

<table>
<thead>
<tr>
<th>Parameters</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageName</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>listControlName</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>controlName</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>operator</td>
<td><a href="#">ExpressionOperator</a></td>
<td></td>
</tr>
<tr>
<td>NAME</td>
<td>TYPE</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------</td>
<td>------------------------------</td>
</tr>
<tr>
<td>value</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**Returns** `DataFilter`

**getFormReference**

getFormReference(componentName: string, filterContext: DataFilter, excludeContext: boolean, filterLocalOnly?: boolean): `NavigationArgs`

Create an `INavigationArgs` object for a specific page/action to be used with a navigation control.

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>componentName</td>
<td>string</td>
<td>Name of the action/page</td>
</tr>
<tr>
<td>filterContext</td>
<td>DataFilter</td>
<td></td>
</tr>
<tr>
<td>excludeContext</td>
<td>boolean</td>
<td></td>
</tr>
<tr>
<td>filterLocalOnly?</td>
<td>boolean</td>
<td></td>
</tr>
</tbody>
</table>

**Returns** `NavigationArgs`

**hideNavigation**

hideNavigation(pageNamesToHide: string[]): any

Hides the specified page(s) from the default landing page. Example:

```javascript
metadataService.hideNavigation('Select-a-customer', 'Select-a-vehicle');
```

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageNamesToHide</td>
<td>string</td>
<td>Page name(s)</td>
</tr>
</tbody>
</table>

**Returns** any
Multi-Lookup control type. Multi-Lookup controls are similar to regular lookups except they allow multiple selections at once.

**Hierarchy**

```
InputControl
    └ MultiLookup
```

**Index**

**Properties**

- `container`
- `generic`
- `getDataSource`
- `getEntityRefs`
- `hidden`
- `setEntityRefs`

**Methods**

- `applyDesign`
- `dataContext`
- `getDesign`
- `getLookupPage`
- `isEditable`
- `metadata`
- `parent`
- `root`

**Events**

- `onDataChanged`

**Properties**

- `container`
  
  container: boolean (optional)

  True if the control is a container.

  Inherited from `Control.container`

- `generic`
  
  generic: boolean (optional)

  Inherited from `Control.generic`

- `getDataSource`
**getDataSource:** function(): any

Inherited from Control.getDataSource

**getEntityRefs**

getEntityRefs: function(): string[] | number[]

**hidden**

hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

**setEntityRefs**

setEntityRefs: function(ids: string[] | number[]): Promise <any>

**Methods**

**applyDesign**

applyDesign(IDesign: MultiLookupDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDesign</td>
<td>MultiLookupDesign</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

**Returns** void

**dataContext**

dataContext(): any

Inherited from Control.dataContext

**Returns** any

**getDesign**

getDesign(): Design

Returns the design object of this control.

Inherited from Control.getDesign

**Returns** Design

**getLookupPage**

getLookupPage(): Page

**Returns** Page
isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

Inherited from Control.isEditable

metadata

metadata(): MultiLookupMetadata

Returns the metadata object of this control.

Overrides InputControl.metadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

Inherited from Control.parent

root

root(): Page

Returns the root form instance (page) of this control.

Inherited from Control.root

Events

onDataChanged

onDataChanged: EventHook <null>

An event that is triggered when the input control’s data changes.

Inherited from InputControl.onDataChanged
Multi-Lookup design object type.

**Hierarchy**

- InputControlDesign
- MultiLookupDesign

**Index**

**Properties**

- `alignItems`
- `alignSelf`
- `bindings`
- `border`
- `color`
- `flexFlow`
- `flexSize`
- `fontSize`
- `fontWeight`
- `justifyItems`
- `label`
- `labelPosition`
- `name`
- `padding`
- `type`

**Properties**

**alignItems**

`alignItems: string (optional)`

This property is an alias for the CSS property "align-items". Please refer to [this web page](#) for documentation on the "align-items" property.

Inherited from `Design.alignItems`

**alignSelf**

`alignSelf: string (optional)`

Inherited from `Design.alignSelf`

**bindings**

`bindings: any (optional)`

Inherited from `Design.bindings`
**border**

`border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)`

The border behavior of a control. This property will not be inherited by the children.

Inherited from Design.border

**color**

`color: string (optional)`

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.

Consider setting the background color at the same time as necessary when setting this attribute.

Note: if color is set to "theme", the theme color of the app will be used.

The following colors are available:

- **blue**: #0078D7
- **pomegranate**: #911844
- **raspberry**: #8D398F
- **darkOrange**: #D24726
- **green**: #369F47
- **blueberry**: #17234E
- **grape**: #432158
- **lightBlue**: #5DB2FF
- **lightGreen**: #82BA00
- **pink**: #DC4FAD
- **teal**: #008299
- **mediumDarkBlue**: #004B8B
- **cordovan**: #570000
- **darkCordovan**: #380000
- **black**: #000000
- **lightGray**: #e8e8e8
- **light**: #fff
- **dark**: #333333

Inherited from Design.color

**flexFlow**

`flexFlow: string (optional)`

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.

Inherited from Design.flexFlow

**flexSize**

`flexSize: string (optional)`
One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to [this web page](#) for documentation on the "flex" property.

<table>
<thead>
<tr>
<th>Inherited from Design.flexSize</th>
</tr>
</thead>
</table>

**fontSize**

`fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)`

The proportional text size

<table>
<thead>
<tr>
<th>Inherited from Design.fontSize</th>
</tr>
</thead>
</table>

**fontWeight**

`fontWeight: "normal" | "bold" (optional)`

Normal or bold text.

<table>
<thead>
<tr>
<th>Inherited from Design.fontWeight</th>
</tr>
</thead>
</table>

**justifyItems**

`justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)`

This property is an alias for the CSS property "justify-content". Please refer to [this web page](#) for documentation on the "justify-content" property.

<table>
<thead>
<tr>
<th>Inherited from Design.justifyItems</th>
</tr>
</thead>
</table>

**label**

`label: string (optional)`

<table>
<thead>
<tr>
<th>Inherited from Design.label</th>
</tr>
</thead>
</table>

**labelPosition**

`labelPosition: "stacked" | "hidden" | "inline" (optional)`

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

<table>
<thead>
<tr>
<th>Inherited from Design.labelPosition</th>
</tr>
</thead>
</table>

**name**

`name: string (optional)`

<table>
<thead>
<tr>
<th>Inherited from Design.name</th>
</tr>
</thead>
</table>

**padding**

`padding: "none" | "small" | "std" (optional)`

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

| Inherited from Design.padding |
**type**

type: `ControlType` (optional)

The type of the control as a string.

Inherited from `Design.type`
Multi-Lookup metadata type.

**Hierarchy**

```
InputControlMetadata
 └ MultiLookupMetadata
```

**Index**

**Properties**

- BoundEntity
- BoundField
- Description
- Design
- Editable
- ExtType
- FilterContext
- FilterLocalOnly
- HelpText
- Hidden
- Id
- Label
- LookupPageId
- Mandatory

**Events**

- OnLookupPageCreate
- OnLookupPageCreated

**Properties**

**BoundEntity**

*BoundEntity*: string (optional)

The entity to which the control is bound.

Inherited from `ControlMetadata.BoundEntity`
BoundField
BoundField: string (optional)

Inherited from ControlMetadata.BoundField

Description
Description: string (optional)

Description of the control.

Inherited from ControlMetadata.Description

Design
Design: Design (optional)

Design object for the lookup page that is referenced by the LookupPageId.

Editable
Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from ControlMetadata.Editable

ExtType
ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from ControlMetadata.ExtType

FilterContext
FilterContext: DataFilter (optional)

FilterLocalOnly
FilterLocalOnly: boolean (optional)

HelpText
HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Inherited from ControlMetadata.HelpText

Hidden
Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Inherited from ControlMetadata.Hidden

Id
Id: string (optional)
Identification string for a control.

Inherited from ControlMetadata.Id

Label
Label: string (optional)
Label for a control. For example, a control representing a person's first name might have a label "First Name".

Inherited from ControlMetadata.Label

LookupPageId
LookupPageId: string (optional)
Page that is hosted within the multi-lookup.

Mandatory
Mandatory: boolean (optional)
If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.

Inherited from InputControlMetadata.Mandatory

Name
Name: string (optional)
Name of a control.

Inherited from ControlMetadata.Name

NumSequence
NumSequence: NumberSequenceConfig (optional)
Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```javascript
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
    referencePageName: 'numSeqReferencePage',
    dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

Inherited from InputControlMetadata.NumSequence

Order
Order: number (optional)
Number indicating the order in which a control will appear on a page.

- **ReferenceAppId**
  ReferenceAppId: string (optional)

- **ReverseLookupRelation**
  ReverseLookupRelation: boolean (optional)

- **ShowPending**
  ShowPending: boolean (optional)

- **Type**
  Type: `ControlType` (optional)

  String indicating the control type.

Inherited from `ControlMetadata.Order` and `ControlMetadata.Type`.

**Events**

- **OnLookupPageCreate**
  OnLookupPageCreate: function(args: any, multiLookup: any): void (optional)

- **OnLookupPageCreated**
  OnLookupPageCreated: function(args: any, multiLookup: any): void (optional)
Hierarchy

PageTarget
   └—— NavigationArgs

Index

Properties

- **label**
  label: string (optional)

- **options**
  options: any (optional)

- **params**
  params: PageOptions (optional)

  Inherited from PageTarget.params

- **replace**
  replace: boolean (optional)

  If set to true, removes current view firing navigation from navigation history stack.

- **to**
  to: string (optional)

  Inherited from PageTarget.to

- **url**
  url: string (optional)

  If provided, this link is directly opened.
Number Sequence Configuration type.

Properties
- **dataType**
  - dataType: string
  - The data type is used to lookup whether the number sequence is editable or not on the reference page.

- **referencePageName**
  - referencePageName: string
  - Page name of the page that defines if the num sequence is editable.
Page object type.

Properties

children
children: Control []
(Read-only) The list of all direct children controls of the page.

dataLoadedInitially
dataLoadedInitially: Promise <void>
(Read-only) A promise which resolves when the data has loaded for the first time. The promise continues to stay resolved for the rest of the page life.

initialized
initialized: boolean
(Read-only) True if the page instance has been initialized.

metadata
metadata: PageMetadata
(Read-only) The page metadata.

metadataLoaded
metadataLoaded: Promise <void>
(Read-only) A promise which resolves when the metadata has finished loading.

pageContext
pageContext: string
The current page context.

pageFilter
pageFilter: DataFilter
The current filter applied on the page.

state
state: PageState
(Read-only) The current state of the page.

syncError
syncError: boolean
(Read-only) True if the page's submission is in error state. This normally happens when the server rejects submissions due to validation errors. Refer to this topic for a detailed explanation of page data synchronization.

syncPending
syncPending: boolean
(Read-only) True if the page's submission is waiting to be synced. Refer to this topic for a detailed explanation of
page data synchronization.

**syncProcessing**

syncProcessing: boolean

(Read-only) True if the page instance is currently syncing its submission. Refer to [this topic](#) for a detailed explanation of page data synchronization.

**syncUnitEditable**

syncUnitEditable: boolean

(Read-only) True if it’s possible to edit a submission while it’s waiting to be synchronized. Refer to [this topic](#) for a detailed explanation of page data synchronization.

**title**

title: string

(Read-only) The title of the page.

## Methods

**canSubmit**

canSubmit(): boolean

Returns true if action page can be submitted and there are no validation/error messages.

**close**

close(): void

Dispose the page instance and all its lifecycle events.

**getAction**

getAction(actionName: string): [PageLink](#)

Get a page action by name. These include the actions in the action sheet/menu.

### Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>actionName</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**getActions**

getActions(): [PageLink](#)[]

Get all page actions. These include the actions in the action sheet/menu.

**getControl**

getControl(controlName: string): [Control](#)

Get a page control by name. It recursively searches through all its children pages.

### Parameters
<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**Returns** Control

**getDesign**

getDesign(): Design

Get the design object associated with the page.

**Returns** Design

**getEntityContext**

gentityContext(): EntityRef

Get current entity context.

**Returns** EntityRef

**isEditable**

isEditable(): boolean

Returns true if the page is an Action Page

**Returns** boolean

**refreshData**

refreshData(): Promise < void>

Force refresh page data.

**Returns** refreshData

**resume**

resume(): Promise < void>

Resume a temporarily suspended page.

**Returns** resume

**submit**

submit(): Promise < CompleteEventArgs>

Submit an Action.

**Returns** submit

**suspend**

suspend(): void

Temporarily suspend a page. For example, when the page is not the active view.

**Returns** suspend

**Events**

**onClose**

onClose: EventHook < null>

Event that is raised when a page is closed.

**onComplete**
onComplete: EventHook <any>

Event that is raised when an action is completed.

**onDataLoaded**

onDataLoaded: EventHook <any>

Event that fires when the page data has loaded. The event may be fired multiple times - every time new data is loaded.

**onInit**

onInit: EventHook <any>

Event that fires when a page instance has been initialized, and the metadata has been loaded.

**onPreInit**

onPreInit: EventHook <any>

Event that fires when a page instance has been initialized. This is fired before the metadata has been loaded.

**onRefresh**

onRefresh: EventHook <null>

Event that fires on forced page refresh, before new data has been loaded.

**onStateChange**

onStateChange: EventHook <null>

Event that fires when the page state changes.

**onSubmit**

onSubmit: EventHook <PageSubmitArgs>

Event that fires before an action is submitted. It can be intercepted for action validation/deferring. Refer to IPageSubmitArgs to know more about the available options.

**onSyncStatusChange**

onSyncStatusChange: EventHook <null>

Event that fires when the page sync status changes.
Represented by the data that is loaded into a page.

**Hierarchy**

**PageData**

**Index**

**Methods**

- `getControlValue`
- `setControlValue`

### Methods

**getControlValue**

```typescript
getControlValue(controlName: string): any
```

Gets the value of a control directly from the data set loaded in the page. The "value" is loosely defined across all different types of controls and generally indicates the primary single field value displayed or interacted with the control. Some complex controls (e.g., a lookup or a list) may not have a simple value and thus cannot be accessed via this API.

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td>name of the control whose value is to be retrieved</td>
</tr>
</tbody>
</table>

**Returns any**

**setControlValue**

```typescript
setControlValue(controlName: string, value: any): any
```

Sets the value of a control directly into the data set loaded in the page. The "value" is loosely defined across all different types of controls and generally indicates the primary single field value displayed or interacted with the control. Some complex controls (e.g., a lookup or a list) may not have a simple value and thus cannot be accessed via this API.

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td>Name of the control whose value is to be set</td>
</tr>
<tr>
<td>value</td>
<td>any</td>
<td>The value to be set</td>
</tr>
</tbody>
</table>

**Returns any**
PageLink type

11/24/2021 • 2 minutes to read • Edit Online

Pagelink control type. A pagelink is a control that navigates to another page.

Hierarchy

Control
  └ PageLink

- isEditable
- metadata
- parent
- root
- showCount

Properties

container

container: boolean (optional)

True if the control is a container.

Inherited from Control.container

generic

generic: boolean (optional)

Inherited from Control.generic

getDataSource

getDataSource: function(): any
hidden
hidden: boolean
True if the control is hidden.

Inherited from Control.hidden

Methods
allowsNavigation
allowsNavigation(): boolean
Returns boolean

applyDesign
applyDesign(design: PageLinkDesign): void
Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>design</td>
<td>PageLinkDesign</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void
dataContext
dataContext(): any

Inherited from Control.dataContext

Returns any
getCount
getCount(): number | string
Returns number | string

getDesign
getDesign(): Design
Returns the design object of this control.

Inherited from Control.getDesign

Returns Design
getNavigationHandler
getNavigationHandler(): NavigationArgs
Returns NavigationArgs
isEditable

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from Control.isEditable

Returns boolean

metadata

metadata(): PageLinkMetadata

Returns the metadata object of this control.

Overrides Control.metadata

Returns PageLinkMetadata

parent

parent(): Control | Page

Returns the parent (control or page) of this control.

Inherited from Control.parent

Returns Control | Page

root

root(): Page

Returns the root form instance (page) of this control.

Inherited from Control.root

Returns Page

showCount

showCount(): boolean

Returns boolean
Pagelink design object type.

**Hierarchy**

**Properties**

- alignItems
- alignSelf
- background
- bindings
- border
- color
- excludedContext
- flexFlow
- flexSize
- fontSize
- fontWeight
- hideArrow
- icon
- justifyItems
- label
- labelPosition
- name
- navigation
- padding
- showCount
- style
- type

**Properties**

**alignItems**

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to [this web page](#) for documentation on the "align-items" property.

| Inherited from Design.alignItems |

**alignSelf**
alignSelf: string (optional)

| Inherited from Design.alignSelf |

**background**

background: string (optional)

Sets the background color. If “theme” is used, then the color will match the app’s theme color.

- **blue:** #0078D7
- **pomegranate:** #911844
- **raspberry:** #8D398F
- **darkOrange:** #D24726
- **green:** #369F47
- **blueberry:** #17234E
- **grape:** #432158
- **lightBlue:** #5DB2FF
- **lightGreen:** #82BA00
- **pink:** #DC4FAD
- **teal:** #008299
- **mediumDarkBlue:** #004B8B
- **cordovan:** #570000
- **darkCordovan:** #380000
- **black:** #000000
- **lightGray:** #E8E8E8
- **light:** #FFF
- **dark:** #333333
- **neutral:** #555555
- **negative:** #D24726

**bindings**

bindings: any (optional)

| Inherited from Design.bindings |

**border**

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

| Inherited from Design.border |

**color**

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.
Consider setting the background color at the same time as necessary when setting this attribute. 

Note: if color is set to “theme”, the theme color of the app will be used.

The following colors are available:

- **blue**: 
  - #0078D7;
- **pomegranate**: 
  - #911844;
- **raspberry**: 
  - #8D398F;
- **darkOrange**: 
  - #D24726;
- **green**: 
  - #369F47;
- **blueberry**: 
  - #17234E;
- **grape**: 
  - #432158;
- **lightBlue**: 
  - #5DB2FF;
- **lightGreen**: 
  - #82BA00;
- **pink**: 
  - #DC4FAD;
- **teal**: 
  - #008299;
- **mediumDarkBlue**: 
  - #004B8B;
- **cordovan**: 
  - #570000;
- **darkCordovan**: 
  - #380000;
- **black**: 
  - #000000;
- **lightGray**: 
  - #e8e8e8;
- **light**: 
  - #fff;
- **dark**: 
  - #333333;

| Inherited from | Design.color |

**excludeContext**

*excludeContext: boolean (optional)*

**flexFlow**

*flexFlow: string (optional)*

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to [this web page](#) for documentation on the "flex-flow" property.

| Inherited from | Design.flexFlow |

**flexSize**

*flexSize: string (optional)*

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to [this web page](#) for documentation on the "flex" property.

| Inherited from | Design.flexSize |

**fontSize**

*fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)*
The proportional text size

| FontWeight
| fontWeight: "normal" | "bold" (optional)
| Normal or bold text.

| hideArrow
| hideArrow: boolean (optional)
| Allows an arrow ( > ) on a default styled navigation control to be hidden. By default, arrows are present in a navigation control. This property can only be added through the design object.

| icon
| icon: string (optional)
| Name of the icon that is displayed in the pagelink control. Here is a list of available icons.

| justifyItems
| justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)
| This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

| label
| label: string (optional)
| Inherited from Design.label

| labelPosition
| labelPosition: "stacked" | "hidden" | "inline" (optional)
| Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

| name
| name: string (optional)
| Inherited from Design.name

| navigation
| navigation: NavigationArgs (optional)
| Navigation object of the pagelink.

| padding
padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

| Inherited from Design.padding |

**showCount**

showCount: boolean (optional)

If true, shows a count of the records present in the list on the target page. This property is only suitable when the navigation target is a Page which contains a List control.

**style**

style: string (optional)

Determines the visual style of the pagelink control. Options:

- "inline": takes up the full width its container, with the label in-line with the icon
- "button": takes up only as much width as needed by the label, with the label below the icon

**type**

type: ControlType (optional)

The type of the control as a string.

| Inherited from Design.type |
Pagelink metadata type.

Properties

BoundEntity
BoundEntity: string (optional)

The entity to which the control is bound.

Inherited from ControlMetadata.BoundEntity

BoundField
BoundField: string (optional)
Inherited from `ControlMetadata.BoundField`

**Description**

Description: string (optional)

Description of the control.

Inherited from `ControlMetadata.Description`

**Editable**

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

Inherited from `ControlMetadata.Editable`

**ExcludeContext**

ExcludeContext: boolean (optional)

**ExtType**

ExtType: `ControlType` (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

Inherited from `ControlMetadata.ExtType`

**HelpText**

HelpText: string (optional)

The keyboard shortcut for a command. For example, 
"(Shift+F5)"

Inherited from `ControlMetadata.HelpText`

**Hidden**

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Inherited from `ControlMetadata.Hidden`

**Icon**

Icon: string (optional)

Name of the icon that is displayed in the page link control. Here is a list of available icons.

**IconSize**

IconSize: number (optional)

Determines the size of the icon that is displayed in the page link control.

**Id**

Id: string (optional)

Identification string for a control.

Inherited from `ControlMetadata.Id`

**Label**
Label: string (optional)
Label for a control. For example, a control representing a person's first name might have a label "First Name".

Inherited from ControlMetadata.Label

Name
Name: string (optional)
Name of a control.

Inherited from ControlMetadata.Name

Navigation
Navigation: NavigationArgs (optional)
Navigation object of the page link.

Order
Order: number (optional)
Number indicating the order in which a control will appear on a page.

Inherited from ControlMetadata.Order

ShowCount
ShowCount: boolean (optional)
If true, shows a count of the records present in the list on the target page. This property is only suitable when the navigation target is a Page which contains on a List control.

Style
Style: string (optional)
Determines the visual style of the page link control. Options:

- "inline": takes up the full width its container, with the label in-line with the icon
- "button": takes up only as much width as needed by the label, with the label below the icon

Target
Target: string (optional)
Name of the target action or page to navigate to when the page link is selected.

Type
Type: ControlType (optional)
String indicating the control type.

Inherited from ControlMetadata.Type

UseDataContext
UseDataContext: boolean (optional)

Events

OnNavigate
OnNavigate: function(navigation: NavigationArgs | string): any (optional)
An event that is triggered when the navigation is triggered.

`cancel`
cancel(): any
Prevent the action from submitting.

Returns any

getMessages
getMessages(): string [ ]
Get all previously added messages

Returns string [ ]

isCancelled
isCancelled(): boolean
Check if the submit action is cancelled.

Returns boolean

wait
wait(promise: Promise <any>): any
Wait on a given promise before continuing with the submission. All promises attached via wait must resolve before the submit action is performed.

Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>

**Properties**

**container**

container: boolean

True if the control is a container.

- Inherited from ContainerControl.container
- Overrides Control.container

**generic**

generic: boolean (optional)

- Inherited from Control.generic
**getDataSource**
getDataSource: function(): any

Inherited from Control.getDataSource

**hidden**
hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

**Methods**

**applyDesign**
applyDesign(IDesign: PartDesign): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Overrides Control.applyDesign

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>

Returns void

**dataContext**

dataContext(): any

Inherited from Control.dataContext

Returns any

**getControl**

getControl(controlName: string): Control

Given the name of a control, returns the control instance.

Inherited from ContainerControl.getControl

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td>control name</td>
</tr>
</tbody>
</table>

Returns Control

**getControlById**

getControlById(id: string): Control

Given the ID of a control, returns the control instance.
### Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
<td>control ID</td>
</tr>
</tbody>
</table>

Returns **Control**

**getDesign**

getDesign(): Design

Returns the design object of this control.

Inherited from **Control.getDesign**

Returns **Design**

**getEntityRef**

gentityRef(): string

Gets value of entityRef binding to control.

Returns **string**

**getPartPage**

getPartPage(): Page

Gets the page of the part.

Returns **Page**

**hasTarget**

hasTarget(): boolean

Returns true if the part has a target page.

Returns **boolean**

**isEditable**

isEditable(): boolean

Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable. Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

Inherited from **Control.isEditable**

Returns **boolean**

**metadata**

metadata(): PartMetadata

Returns the metadata object of this control.

Overrides **ContainerControl.metadata**
**Returns** PartMetadata

**parent**

parent(): Control | Page

Returns the parent (control or page) of this control.

| Inherited from Control.parent |

**Returns** Control | Page

**root**

root(): Page

Returns the root form instance (page) of this control.

| Inherited from Control.root |

**Returns** Page
Part design object type.

**Hierarchy**

- padding
- target
- type

**Properties**

**alignItems**

alignItems: string (optional)

This property is an alias for the CSS property "align-items". Please refer to this web page for documentation on the "align-items" property.

Inherited from Design.alignItems

**alignSelf**

alignSelf: string (optional)
allowScroll
allowScroll: string (optional)

True if the container will allow scrolling when its items do not fit into the container’s available space. If a container has an item which may scroll, then set this property to false to prevent nested scrolling areas.

background
background: string (optional)

The background color of the container. Consider modifying the color attribute in the same container so that fonts overlaying the background color will appear appropriately. Note: if background is set to "theme", the theme color of the app will be used. The following colors are available:

- blue: #0078D7
- pomegranate: #911844
- raspberry: #8D398F
- darkOrange: #D24726
- green: #369F47
- blueberry: #17234E
- grape: #432158
- lightBlue: #5DB2FF
- lightGreen: #82BA00
- pink: #DC4FAD
- teal: #008299
- mediumDarkBlue: #004B8B
- cordovan: #570000
- darkCordovan: #380000
- black: #000000
- lightGray: #e8e8e8
- light: #fff
- dark: #333333

bindings
bindings: any (optional)

border
border: “none” | “solid” | “left” | “right” | “top” | “bottom” (optional)

The border behavior of a control. This property will not be inherited by the children.
**color**

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.

Consider setting the background color at the same time as necessary when setting this attribute.

Note: if color is set to “theme”, the theme color of the app will be used.

The following colors are available:

- **blue**: #0078D7
- **pomegranate**: #911844
- **raspberry**: #8D398F
- **darkOrange**: #D24726
- **green**: #369F47
- **blueberry**: #17234E
- **grape**: #432158
- **lightBlue**: #5DB2FF
- **lightGreen**: #82BAA0
- **pink**: #DC4FAD
- **teal**: #008299
- **mediumDarkBlue**: #004B8B
- **cordovan**: #570000
- **darkCordovan**: #380000
- **black**: #000000
- **lightGray**: #e8e8e8
- **light**: #fff
- **dark**: #333333

---

**design**

design: PartDesign (optional)

Design for the target page.

**flexFlow**

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property “flex-flow”. Please refer to [this web page](#) for documentation on the “flex-flow” property.

---

**flexSize**

flexSize: string (optional)
One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to [this web page](#) for documentation on the "flex" property.

| Inherited from Design.flexSize |

**fontSize**

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

| Inherited from Design.fontSize |

**fontWeight**

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

| Inherited from Design.fontWeight |

**itemBorder**

itemBorder: "solid" | "none" (optional)

If true, a border will appear around each row in the list. This property is equivalent to applying the border property individually to all items in the container.

| Inherited from ContainerControlDesign.itemBorder |

**items**

items: string | Design [ ] (optional)

An array containing the components to place inside of the container.

| Inherited from ContainerControlDesign.items |

**justifyItems**

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to [this web page](#) for documentation on the "justify-content" property.

| Inherited from Design.justifyItems |

**label**

label: string (optional)

| Inherited from Design.label |

**labelPosition**

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

| Inherited from Design.labelPosition |
name
name: string (optional)

Inherited from Design.name

padding
padding: "none" | "small" | "std" (optional)

Allows specifying the component’s padding behavior. A component will inherit the padding behavior specified by its parent container components.

Inherited from Design.padding

target
target: PageTarget (optional)

Target page of the part.

type
type: ControlType (optional)

The type of the control as a string.

Inherited from Design.type
Part metadata type.

Properties

**BoundEntity**
BoundEntity: string (optional)
The entity to which the control is bound.

Inherited from ControlMetadata.BoundEntity

**BoundField**
BoundField: string (optional)

Inherited from ControlMetadata.BoundField

**Description**
Description: string (optional)

Description of the control.

Inherited from ControlMetadata.Description
**Design**

Design: `PartDesign` (optional)

Design for the target page.

**Editable**

Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control's edit-ability and its parent's edit-ability is undefined.

| Inherited from | ControlMetadata.Editable |

**ExtType**

ExtType: `ControlType` (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

| Inherited from | ControlMetadata.ExtType |

**HelpText**

HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

| Inherited from | ControlMetadata.HelpText |

**Hidden**

Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

| Inherited from | ControlMetadata.Hidden |

**Id**

Id: string (optional)

Identification string for a control.

| Inherited from | ControlMetadata.Id |

**Label**

Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

| Inherited from | ControlMetadata.Label |

**Name**

Name: string (optional)

Name of a control.

| Inherited from | ControlMetadata.Name |
**Order**
Order: number (optional)

Number indicating the order in which a control will appear on a page.

| Inherited from | ControlMetadata.Order |

**Target**
Target: PageTarget (optional)

Target page of the part.

**Type**
Type: ControlType (optional)

String indicating the control type.

| Inherited from | ControlMetadata.Type |
Row controls are what make up a list. A list contains any number of row controls.

- isEntitySyncPending
- select

**Properties**

**fieldList**
fieldList: Control []

**headerField**
headerField: Control

**hidden**
hidden: boolean
If true then the row will be hidden.

**imageFields**
imageFields: Control []
**isSelected**

isSelected: boolean

**item**

item: any

A container of rendered data.

**template**

template: Group

Group control that represents the template for a row.

## Methods

**getControl**

getControl(controlName: string): Control

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlName</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**Returns** Control

**getControlById**

getControlById(id: string): Control

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
<td>id can be valueKey or the displayKey of the list control metadata</td>
</tr>
</tbody>
</table>

**Returns** Control

**getControlValueById**

getControlValueById(id: string): string

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>string</td>
<td>id can be valueKey or the displayKey of the list control metadata</td>
</tr>
</tbody>
</table>

**Returns** string

**getRowHeader**

getRowHeader(): Control

**Returns** Control

**getRowId**

getRowId(): string

**Returns** string

**hasImageField**
hasImageField(): boolean

Returns true if the row has an image field.

Returns boolean

isEntityCreatedNew

isEntityCreatedNew(): boolean

Returns boolean

isEntityDeleted

isEntityDeleted(): boolean

Returns boolean

isEntityModified

isEntityModified(): boolean

Returns boolean

isEntitySyncPending

isEntitySyncPending(): boolean

Returns boolean

select

select(): any

Returns any
Value control type. This is the base class for single value controls.

generic
generic: boolean (optional)

| Inherited from Control.generic |
**getDataSource**

getDataSource: function(): any

Inherited from Control.getDataSource

**hidden**

hidden: boolean

True if the control is hidden.

Inherited from Control.hidden

## Methods

### applyDesign

applyDesign(design: Design): void

Applies given design to the design on the control. If a design already exists, the prototype chain of the design will be preserved.

Inherited from Control.applyDesign

### Parameters

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>design</td>
<td>Design</td>
<td>object containing design properties as keys</td>
</tr>
</tbody>
</table>

Returns void

### dataContext

dataContext(): any

Inherited from Control.dataContext

Returns any

### getDesign

getDesign(): Design

Returns the design object of this control.

Inherited from Control.getDesign

Returns Design

### getValue

getValue(): string

Returns the value of the control.

Returns string

### isEditable

isEditable(): boolean
Boolean indicating if the control is editable. Returns false when either the control or its parent is not editable.
Returns true when both the control and its parent are editable. Returns true when either the control or its parent is editable and the other is undefined. Returns undefined if both the control's edit-ability and its parent's edit-ability is undefined.

<table>
<thead>
<tr>
<th>Inherited from Control.isEditable</th>
</tr>
</thead>
</table>

**Returns** boolean

**metadata**

metadata(): ValueMetadata

Returns the metadata object of this control.

<table>
<thead>
<tr>
<th>Overrides InputControl.metadata</th>
</tr>
</thead>
</table>

**Returns** ValueMetadata

**parent**

parent(): Control | Page

Returns the parent (control or page) of this control.

<table>
<thead>
<tr>
<th>Inherited from Control.parent</th>
</tr>
</thead>
</table>

**Returns** Control | Page

**root**

root(): Page

Returns the root form instance (page) of this control.

<table>
<thead>
<tr>
<th>Inherited from Control.root</th>
</tr>
</thead>
</table>

**Returns** Page

**setValue**

setValue(value: string): void

Sets the value of the control.

**Parameters**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>string</td>
<td></td>
</tr>
</tbody>
</table>

**Returns** void

**Events**

**onDataChanged**

onDataChanged: EventHook <null>

An event that is triggered when the input control's data changes.

| Inherited from InputControl.onDataChanged |
Value design object type.

**Hierarchy**

```
InputControlDesign
  └ ValueDesign
    └ FileUploaderDesign
    └ HyperLinkDesign
```

**Index**

**Properties**

- `alignItems`
- `alignSelf`
- `bindings`
- `border`
- `color`
- `flexFlow`
- `flexSize`
- `fontSize`
- `fontWeight`
- `justifyItems`
- `label`
- `labelPosition`
- `name`
- `padding`
- `type`

**Properties**

**alignItems**

`alignItems: string (optional)`

This property is an alias for the CSS property "align-items". Please refer to [this web page](#) for documentation on the "align-items" property.

Inherited from Design.alignItems

**alignSelf**

`alignSelf: string (optional)`

Inherited from Design.alignSelf

**bindings**

`bindings: any (optional)`
border

border: "none" | "solid" | "left" | "right" | "top" | "bottom" (optional)

The border behavior of a control. This property will not be inherited by the children.

color

color: string (optional)

The foreground color of the container. This will modify the color of all headers, items, labels, and icons within the container.

Consider setting the background color at the same time as necessary when setting this attribute.

Note: if color is set to "theme", the theme color of the app will be used.

The following colors are available:

- blue: #0078D7;
- pomegranate: #911844;
- raspberry: #8D398F;
- darkOrange: #D24726;
- green: #369F47;
- blueberry: #17234E;
- grape: #432158;
- lightBlue: #5DB2FF;
- lightGreen: #82BA00;
- pink: #DC4FAD;
- teal: #008299;
- mediumDarkBlue: #004B8B;
- cordovan: #570000;
- darkCordovan: #380000;
- black: #000000;
- lightGray: e8e8e8;
- light: #fff;
- dark: #333333;

flexFlow

flexFlow: string (optional)

Specifying this property makes the component a flex container component. This property is an alias for the CSS property "flex-flow". Please refer to this web page for documentation on the "flex-flow" property.
flexSize: string (optional)

One number or two numbers written as a string. For example, "(size to grow) [(size-to-shrink)]" to accommodate available space in the immediate flex container. This property is an alias for the CSS property "flex". Please refer to this web page for documentation on the "flex" property.

Inherited from Design.flexSize

fontSize

fontSize: "medium" | "xx-small" | "x-small" | "small" | "large" | "x-large" | "xx-large" (optional)

The proportional text size

Inherited from Design.fontSize

fontWeight

fontWeight: "normal" | "bold" (optional)

Normal or bold text.

Inherited from Design.fontWeight

justifyItems

justifyItems: "flex-start" | "flex-end" | "center" | "space-between" (optional)

This property is an alias for the CSS property "justify-content". Please refer to this web page for documentation on the "justify-content" property.

Inherited from Design.justifyItems

label

label: string (optional)

Inherited from Design.label

labelPosition

labelPosition: "stacked" | "hidden" | "inline" (optional)

Determines how a label is positioned, if at all. By default, labelPosition is set to stacked.

Inherited from Design.labelPosition

name

name: string (optional)

Inherited from Design.name

padding

padding: "none" | "small" | "std" (optional)

Allows specifying the component's padding behavior. A component will inherit the padding behavior specified by its parent container components.

Inherited from Design.padding
**type**

type: ControlType (optional)

The type of the control as a string.

Inherited from Design.type
ValueMetadata type

Value metadata type.

Hierarchy

InputControlMetadata
   └ ValueMetadata
      └ FileUploaderMetadata
      └ HyperLinkMetadata

Properties

- BoundEntity
- BoundField
- Description
- Editable
- ExtType
- HelpText
- Hidden
- Id
- Label
- Mandatory
- Name
- NumSequence
- Order
- Type

Properties

**BoundEntity**

BoundEntity: string (optional)

The entity to which the control is bound.

Inherited from ControlMetadata.BoundEntity

**BoundField**

BoundField: string (optional)

Inherited from ControlMetadata.BoundField

**Description**

Description: string (optional)

Description of the control.
Editable
Editable: boolean (optional)

Boolean indicating if the control is editable. False when either the control or its parent is not editable. True when both the control and its parent are editable. True when either the control or its parent is editable and the other is undefined. Undefined if both the control’s edit-ability and its parent’s edit-ability is undefined.

ExtType
ExtType: ControlType (optional)

The extended control type. For example, a control of type Input might have an extended type of Barcode.

HelpText
HelpText: string (optional)

The keyboard shortcut for a command. For example, "(Shift+F5)"

Hidden
Hidden: boolean (optional)

Boolean indicating if the control is hidden or not.

Id
Id: string (optional)

Identification string for a control.

Label
Label: string (optional)

Label for a control. For example, a control representing a person's first name might have a label "First Name".

Mandatory
Mandatory: boolean (optional)

If set to true then input for the control is required for the task to be completed. Mandatory controls will have a red outline.
**Name**

Name: string (optional)

Name of a control.

Inherited from ControlMetadata.Name

**NumSequence**

NumSequence: NumberSequenceConfig (optional)

Used for auto detecting and changing visibility of the number sequence controls in the task or page, based on AX number sequence configuration, through extended business logic. Example:

```javascript
// hide number sequence reference page from users
metadataService.hideNavigation('numSeqReferencePage');

// parameters to be passed to 'numSequence' flag in configureControl
var configParam = {
    referencePageName: 'numSeqReferencePage',
    dataType: 'HcmPersonnelNumberId'
};

// setup 'PersonnelNumber' control as number sequence in the task 'add-worker'
metadataService.configureControl('add-worker', 'PersonnelNumber', { numSequence: configParam });
```

Inherited from InputControlMetadata.NumSequence

**Order**

Order: number (optional)

Number indicating the order in which a control will appear on a page.

Inherited from ControlMetadata.Order

**Type**

Type: ControlType (optional)

String indicating the control type.

Inherited from ControlMetadata.Type
Process automation enables simple scheduling of processes that will be run by the batch server. The process automation framework is a set of APIs that lets you implement process automation.

You should use only the public APIs to implement process automation, and you should follow these guidelines:

- Don't select from, insert into, or directly reference the process automation tables.
- Don't extend the framework or integrate your code with the classes.
- Don't subscribe to table events such as insert, update, and delete. Finance and Operations apps skip most of those events.
- If functionality that you require is missing, submit feature requests.

Microsoft plans to add features in the future. If you integrate too deeply with the process automation framework, your integration might break when those features are added.

Some of the examples for the process automation framework aren’t representative of release-quality code. As always, the expectation is that processes that are built by using the framework will follow all best practices and quality standards.

For more information about process automation, see Process automation.

### Definitions

<table>
<thead>
<tr>
<th>TERM</th>
<th>DEFINITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Poller</td>
<td>The poller is a system-critical batch process that runs every minute and invokes various subsystems of the process automation framework. It consults the schedule to determine which processes are ready to run, and then it invokes the runtime side of the framework to ensure that processes are run.</td>
</tr>
<tr>
<td>Scheduled process</td>
<td>A scheduled process is a process that is scheduled in the user interface (UI) by a user. Occurrences for these processes can be seen in a calendar view.</td>
</tr>
<tr>
<td>Background process</td>
<td>A background process is also known as a polled process. It’s a process that runs frequently, without requiring user input, and performs some background processing. Subledger transfer to the general ledger is an example.</td>
</tr>
<tr>
<td>Type</td>
<td>In this topic and related topics, the term type refers to ProcessScheduleType, as discussed in Type registration.</td>
</tr>
<tr>
<td>Series</td>
<td>Every process that has a registered type must have a series. Series for scheduled processes are created in the UI by users. Series for background processes are created through series registration. For more information, see Series registration.</td>
</tr>
<tr>
<td>Date and time</td>
<td>All framework dates are stored in Coordinated Universal Time (UTC) but shown in the user's preferred time zone.</td>
</tr>
</tbody>
</table>
## Tasks

Implementation of a process automation solution consists of a set of tasks, some of which are required and some of which are optional.

Most of the UI customizations aren't supported for background processes. The **Series** list page and logging of results and messages are supported.

<table>
<thead>
<tr>
<th>TASK</th>
<th>REQUIRED FOR A SCHEDULED PROCESS</th>
<th>REQUIRED FOR A BACKGROUND PROCESS</th>

<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Customize the user interface</td>
<td>No</td>
<td>See Customize the user interface.</td>
</tr>
</tbody>
</table>
To implement a process by using the process automation framework, you must first understand the concept of a type in the framework. A type is a unique process that is integrated with the batch framework and that uses the SysOperations framework, specifically the SysOperationServiceController class. The types are stored in the ProcessScheduleType table.

Here are a few examples of different types that are registered with the process automation framework:

- Vendor Payment Proposal (VendPaymProposalAutomationTypeRegistrationProvider class)
- Vendor Invoice Posting (VendInvoicePostProcessScheduleTypeRegistration class)
- Subledger transfer to general ledger (SubledgerJournalVoucherTransferServiceRegistration class)

If an existing process uses RunBaseBatch, consider wrapping it with SysOperationServiceController. The process automation framework doesn't support RunBaseBatch.

To register your type with the process automation framework, you must implement the ProcessScheduleITypeRegistration interface. This interface has a single method that returns an instance of ProcessScheduleTypeRegistrationItem.

If your process uses a feature flag, you must disable and enable the type as the feature is disabled and enabled, respectively.

- If you disable the feature flag for a type, the type doesn't appear in the user interface (UI). The scheduler won't schedule any occurrences or background processes of that type to run, and the runtime side of the process automation framework won't create any batch jobs for that type.
- If you enable the feature flag for a type, any occurrences or background processes that are scheduled to run in the past will be run immediately. Usually, this behavior is what you want. However, if it isn't what you want, consider disabling any series that is related to the type before you disable the feature flag.

Feature management has events that you can subscribe to. The method that you use to enable and disable types is ProcessScheduleTypeRegistration.enableOrDisableType.

Every time that a database synchronization runs, types and series are updated from their definitions in code. The only background settings that aren't updated are those that can be edited by the system admin. The process automation framework does this update by hooking SysSetup. The system admin can manually trigger this update through the settings at System administration > Setup > Initialize background.

The following example shows a process for a scheduled type. Note the following points:

- A background process doesn't have to set the Parameter tab list, because background processes don't support parameters.
- The type name isn't shown in the UI. The name should be a developer-created string such as VendorInvoiceBatchPosting. It's used internally as a key to reference your type for various purposes. It cannot be a label.
- The type name is used heavily with the SysPlugIn pattern. Most of the interfaces that are implemented for the process automation framework follow the SysPlugIn pattern and require that the type name be supplied by the ExportMetadataAttribute. In most cases in this pattern, the framework invokes the implementation of an interface only for the type that is being operated on, not for other types. Code examples in this topic and related topics follow this pattern.

**ProcessScheduleTypeRegistrationItem class**

The `ProcessScheduleTypeRegistrationItem` class is used as a part of type registration and contains information that is specific to your type.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public ProcessScheduleTypeName parmName(ProcessScheduleTypeName _name = name)</td>
<td>The type name that is passed to the <code>item.parmName</code> method isn't shown to users. This value is a developer-defined string that is used when various events are invoked. It should be assigned as a constant, not as a label. <strong>Never use a label as a type name.</strong> Use names such as <code>VendPaymentProposal</code>.</td>
</tr>
<tr>
<td>public ProcessScheduleProcessType parmScheduleType(ProcessScheduleProcessType _scheduleType = scheduleType)</td>
<td>This method determines whether the process is scheduled or polled.</td>
</tr>
<tr>
<td>public ProcessScheduleCompanyScope parmCompanyScope(ProcessScheduleCompanyScope _companyScope = companyScope)</td>
<td>This method determines whether the process is a single-company process or a global process. A single-company process sets the company context in a batch, depending on the company that the user is in when a series is created. If the scope is global, the company context is ignored, and all jobs are in <code>dat</code>.</td>
</tr>
<tr>
<td>public LabelId parmLabelId(LabelId _labelId = labelId)</td>
<td>The label that this method returns is shown to users and represents the display name for your type. An example is <code>Vendor payment proposal</code>.</td>
</tr>
<tr>
<td>public className parmProcessAutomationTaskClassName(ClassName _processAutomationTaskClassName = processAutomationTaskClassName)</td>
<td>The class name that this method returns is the class name of the class that will implement the <code>ProcessAutomationTask</code> interface.</td>
</tr>
<tr>
<td>public NoYes parmIsEnabled(NoYes _isEnabled = isEnabled)</td>
<td>This method determines whether the type that you're registering is enabled by default. If your type is feature-managed, a default value is taken from the state of the feature. Be sure to implement the enabled and disabled feature management events. Enable and disable your type in the process automation framework in the appropriate way, by using <code>ProcessScheduleTypeRegistration.enableOrDisableType</code> method. Example code is shown earlier in this topic.</td>
</tr>
<tr>
<td>public List parmParameterTabItemList(List _parameterTabList = parameterTabList)</td>
<td>A process can have many parameter pages in the UI. These parameter pages contain parameters that are specific to the process. They are surfaced as form parts in the <strong>Create series</strong> wizard and edit occurrence dialog box. For each parameter page, an instance of the <code>ProcessScheduleTypeRegistrationParameterTabItem</code> class must be constructed and returned in the list. If the process doesn't require parameter pages, return <code>null</code>. For more information, see <code>Process parameters</code>.</td>
</tr>
</tbody>
</table>

**ProcessScheduleTypeRegistrationParameterTabItem class**

The `ProcessScheduleTypeRegistrationParameterTabItem` class represents information that is specific to a
The `Create series` wizard supports parameter pages by using embedded form parts. This value is the menu item that goes to the form part that is created by the team that owns the process.

### METHOD

<table>
<thead>
<tr>

<td>The caption on the parameter page.</td>
</tr>
<tr>
<td>public LabelId parmHelpText(LabelId _helpText = helpText)</td>
<td>The Help text for the parameter page.</td>
</tr>
<tr>
<td>public static ProcessScheduleTypeRegistrationParameterTabItem newFromMenuItem(MenuItemName _menuItemName)</td>
<td>Constructor that initializes the instance with the specified menu item name.</td>
</tr>
</tbody>
</table>
Every process must have a series. The concept of a series in process automation resembles the concept of a meeting series in Microsoft Outlook. However, a series in process automation is a series of scheduled runs of a process. For most scheduled process types, users create the series in the user interface (UI), and series registration never has to be implemented. However, if the process that is being implemented is a schedule series, you can skip this task.

Background processes typically create a series via code, by using series registration, because background processes tend to be "under the hood" processes that don't allow for user interaction. To create a series via code, you implement the `ProcessScheduleISeriesRegistration` interface. This interface contains a single method that returns an instance of `ProcessScheduleSeriesRegistrationItem`.

The process automation framework lets system admins change the default polling interval and unit for background processes.

Here is an example of a test series that is used to test the process automation framework.
using System.ComponentModel.Composition;

// Implements the ProcessScheduleISeriesRegistration to register the vendor invoice batch posting task 'Series' with the Process Automation.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleISeriesRegistration))]
[ExportMetadata(classStr(ProcessScheduleISeriesRegistration),
  classStr(VendInvoicePostProcessScheduleSeriesRegistration))]
internal final class VendInvoicePostProcessScheduleSeriesRegistration implements ProcessScheduleISeriesRegistration
{

    [Hookable(false)]
    public ProcessScheduleSeriesRegistrationItem
    getProcessScheduleSeriesRegistrationItem()
    {
        ProcessScheduleSeriesRegistrationItem
        processScheduleSeriesRegistrationItem =
        ProcessScheduleSeriesRegistrationItem::construct();
        processScheduleSeriesRegistrationItem.parmDescription("@AccountsPayable:VendInvoicePostTaskFeatureSummary");
        processScheduleSeriesRegistrationItem.parmOwnerId(curUserId());
        processScheduleSeriesRegistrationItem.parmProcessScheduleSeriesPatternList(this.getSeriesPatternList());
        processScheduleSeriesRegistrationItem.parmSeriesName("@AccountsPayable:VendInvoicePostTaskFeatureLabel");
        processScheduleSeriesRegistrationItem.parmTypeName(VendInvoicePostTaskConstants::VendorInvoiceBatchPosting);
        return processScheduleSeriesRegistrationItem;
    }

    private List
    getSeriesPatternList()
    {
        ProcessScheduleSeriesPatternItem
        processScheduleSeriesPatternItem =
        ProcessScheduleSeriesPatternItem::construct();
        processScheduleSeriesPatternItem.parmUnit(ProcessScheduleUnit::Minute);
        processScheduleSeriesPatternItem.parmPollingInterval(VendParameters::pollingIntervalMinutes());
        List list = new List(Types::Class);
        list.addEnd(processScheduleSeriesPatternItem);
        return list;
    }
}

ProcessScheduleSeriesRegistrationItem class

</table>

### Modifying background processes

System admins can modify the polling interval and unit in the process automation framework. However, many background processes that currently exist have their own specific UI that is built to manage these changes. Microsoft provides a way to programmatically modify these values via the following APIs.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public static ProcessScheduleSeriesPollingDetails</td>
<td>Gets the polling interval, the unit, and the next scheduled date/time for a</td>
</tr>
<tr>
<td>getPollingDetailsForSeries(ProcessScheduleTypeName _typeName,</td>
<td>polled process.</td>
</tr>
<tr>
<td>ProcessScheduleSeriesName _seriesName)</td>
<td></td>
</tr>
<tr>
<td>public static void</td>
<td>Enables changes to the polling interval, the unit, and the next scheduled</td>
</tr>
<tr>
<td>setPollingDetailsForSeries(ProcessScheduleTypeName _typeName,</td>
<td>date/time for a polled process.</td>
</tr>
<tr>
<td>ProcessScheduleSeriesName _seriesName,</td>
<td></td>
</tr>
<tr>
<td>ProcessScheduleSeriesPollingDetails _pollingDetails)</td>
<td></td>
</tr>
</tbody>
</table>

### Validating background process settings

In version 10.0.13, the process automation framework lets system admins modify background process settings via the **Edit background process** section. Some background processes have restrictions on the frequency of their runs. Microsoft has introduced an interface that a background process can implement. When this interface is invoked, it enables the background process to ensure that the unit and polling interval are within their allowed range.

The following example prevents this process from ever being run every minute or every hour. The process can run a maximum of one time per day. However, a process can implement the rules in such a way that more frequent runs are required.
using System.ComponentModel.Composition;

// Provider to validate background settings.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleISeriesValidateBackgroundDialog))]
[ExportMetadata(extendedTypeStr(ProcessScheduleTypeName), 'ProcessAutomationExploder')]
internal final class ProcessScheduleExplodeAutomationBackgroundDialogValidationProvider implements ProcessScheduleISeriesValidateBackgroundDialog
{
    public boolean validateBackgroundProcessParameters(ProcessScheduleSeriesBackgroundValidationParameters _validationParameters)
    {
        ProcessScheduleUnit currentUnit = _validationParameters.parmUnit();
        if (currentUnit == ProcessScheduleUnit::Minute || currentUnit == ProcessScheduleUnit::Hour)
        {
            SysDictEnum enum = new SysDictEnum(enumNum(ProcessScheduleUnit));
            throw Error(strFmt("@ProcessAutomationFramework:ProcessScheduleExplodeProcessInvalidUnit", 
            enum.value2Label(ProcessScheduleUnit::Minute),
            enum.value2Label(ProcessScheduleUnit::Hour)));
        }
        return true;
    }
}

ProcessScheduleISeriesValidateBackgroundDialog interface
The ProcessScheduleISeriesValidateBackgroundDialog interface enables background processes to validate user input when users edit background settings via ProcessScheduleSeriesBackgroundDialog.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean validateBackgroundProcessParameters(ProcessScheduleSeriesBackgroundValidationParameters _validationParameters)</td>
<td>Implements any validation rules that you have for the process.</td>
</tr>
</tbody>
</table>

ProcessScheduleSeriesBackgroundValidationParameters class
The ProcessScheduleSeriesBackgroundValidationParameters class contains the validation parameters that are validated for the background processes that are being edited.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public UserId parmOwnerId(UserId _ownerId = ownerId)</td>
<td>The owner of the process. It will be used when batch jobs are created, because batch jobs will be created under this user’s context.</td>
</tr>
<tr>
<td>public ProcessScheduleUnit parmUnit(ProcessScheduleUnit _unit = unit)</td>
<td>The unit of time.</td>
</tr>
<tr>
<td>public ProcessScheduleInterval parmPollingInterval(ProcessScheduleInterval _pollingInterval = pollingInterval)</td>
<td>The polling interval. It defines the number of units of time (as specified by parmUnit()) that the process should be run.</td>
</tr>
<tr>
<td>public ProcessScheduleDateTime parmPolledNextScheduledDateTime(ProcessScheduleDateTime _polledNextScheduledDateTime = polledNextScheduledDateTime)</td>
<td>The next scheduled run of the process in Coordinated Universal Time (UTC).</td>
</tr>
<tr>
<td>METHOD</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>public ProcessScheduleDateTime parmSleepFromTime(ProcessScheduleDateTime _polledSleepFromTime = polledSleepFromTime)</td>
<td>Specifies when the sleep should start. The process automation framework lets system admins put a process to sleep for a time range. The process isn't run during this time range, regardless of the setting of parmPolledNextScheduleDateTime(). This time range is a maximum of 16 hours and can span the date boundary.</td>
</tr>
<tr>
<td>public ProcessScheduleDateTime parmSleepToTime(ProcessScheduleDateTime _polledSleepToTime = polledSleepToTime)</td>
<td>Specifies when the sleep should end. The process automation framework lets system admins put a process to sleep for a time range. The process isn't run during this time range, regardless of the setting of parmPolledNextScheduleDateTime(). This time range is a maximum of 16 hours and can span the date boundary.</td>
</tr>
</tbody>
</table>
In most cases, a process must store custom parameters that are specific to its processes. For example, a process might require a date range or a customer number. You must create your own user interface (UI) and custom tables to show and store these parameters. If a type doesn’t have any parameters, you can skip this task.

When a user creates a series in the UI, the Create series wizard hosts multiple form parts, each of which contains a related set of parameters. The form parts for the process contain the UI that the user uses to enter the parameters. These form parts are built by the developer of the process and provided through type registration. A form part implements interfaces that let you initialize, validate, and write the custom parameters.

The custom parameter tables typically have two types of records:

- A template record that is bound to the series that serves as a template for all occurrences.
- A record that is specific to an occurrence and contains the parameters that will be used when that occurrence runs. Users can override the parameters for each occurrence as they require.

Parameter tables typically have one foreign key (RecId) to the ProcessScheduleSeries table and another foreign key (RecId) to the ProcessScheduleOccurrence table. The template record has a series foreign key, but it doesn’t have a foreign key to the occurrence. All other records have both foreign keys.

The following interfaces are used to maintain these parameters.

**ProcessScheduleParametersIInitialize interface**

The ProcessScheduleParametersIInitialize interface lets you initialize parameters when the user interacts with the UI of the process automation framework. The form part that is built for the wizard that shows process-specific parameters implements this interface.

**ProcessScheduleParametersIValidate interface**

The ProcessScheduleParametersIValidate interface lets you validate the parameters that the user enters in the form part.

**ProcessScheduleParametersIWrite interface**

The ProcessScheduleParametersIWrite interface lets you write the parameters to their custom parameter tables.

**Example**

In the following example, the three interfaces that were just described are used for a sample test process. In this example, the form part contains a single string that is known as a message.

```java
[Form]
public class ProcessScheduleSampleUptakeFirstFormPart
extends ProcessScheduleParametersFormPart
implements ProcessScheduleParametersIWrite, ProcessScheduleParametersIValidate,
ProcessScheduleParametersIInitialize
{
    private ProcessScheduleSchedulingContract schedulingContract;
```

public void setSchedulingContract(ProcessScheduleSchedulingContract _schedulingContract) {
  schedulingContract = _schedulingContract;
}

public void initializeForSeriesCreate() {
  String text = StringFmt("@ProcessAutomationFramework:ProcessScheduleSeriesTestTypeInitSeriesCreate", curExt());
  ProcessScheduleSampleUptakeParameters_Message.text(text);
}

public void initializeForSeriesUpdate() {
  ProcessScheduleSampleUptakeParameters parameters =
  ProcessScheduleSampleUptakeParameters::findForProcessScheduleSeries(schedulingContract.processScheduleSeries,
  true);
  ProcessScheduleSampleUptakeParameters_Message.text(parameters.Message);
}

public void initializeForOccurrenceCreate() {
  String text = StringFmt("@ProcessAutomationFramework:ProcessScheduleSeriesTestTypeInitOccurrenceCreate", curExt());
  ProcessScheduleSampleUptakeParameters_Message.text(text);
}

public void initializeForOccurrenceUpdate() {
  ProcessScheduleSampleUptakeParameters parameters =
  ProcessScheduleSampleUptakeParameters::findForProcessScheduleOccurrence(schedulingContract.processScheduleOccurrence);
  ProcessScheduleSampleUptakeParameters_Message.text(parameters.Message);
}

public void createScheduleSeries(ProcessScheduleSchedulingContract _schedulingContract) {
  ProcessScheduleSampleUptakeParameters sampleParameters;
  sampleParameters.Message = ProcessScheduleSampleUptakeParameters_Message.valueStr();
  sampleParameters.insert();
}

public void updateScheduleSeries(ProcessScheduleSchedulingContract _schedulingContract) {
  ProcessScheduleSampleUptakeParameters parameters =
  ProcessScheduleSampleUptakeParameters::findForProcessScheduleSeries(_schedulingContract.processScheduleSeries, true);
  if (parameters) {
    ttsbegin;
    parameters.Message = ProcessScheduleSampleUptakeParameters_Message.valueStr();
    parameters.update();
    ttscommit;
  }
}

public void createScheduledOccurrence(ProcessScheduleSchedulingContract _schedulingContract) {
  ProcessScheduleSampleUptakeParameters occurrenceParameters;
}
public void updateScheduledOccurrence(ProcessScheduleSchedulingContract _schedulingContract) {
    ProcessScheduleSampleUptakeParameters parameters = ProcessScheduleSampleUptakeParameters::findForProcessScheduleOccurrence(_schedulingContract.processScheduleOccurrence, true);

ttsbegin;

    parameters.Message = ProcessScheduleSampleUptakeParameters_Message.valueStr();

    if (parameters.RecId != 0) {
        parameters.update();
    } else {
        parameters.insert();
    }

ttscommit;
}

public boolean validate() {
    boolean isValid = true;
    if (ProcessScheduleSampleUptakeParameters_Message.valueStr() == '') {
        isValid = checkFailed("@ProcessAutomationFramework:ProcessScheduleSeriesTestTypeMessageWarning");
    }
    return isValid;
}

ProcessScheduleIDeleteOccurrence interface

Implement the ProcessScheduleIDeleteOccurrence interface to receive an event that indicates that a user or the system has deleted occurrences. The parameters that are related to that occurrence should be deleted.

This interface is invoked via SysPlugin for a specific type. Use the type name that was created when the type was registered.

Note that a Microsoft Azure SQL Database temp table is passed in so that you can do set-based deletes.
using System.ComponentModel.Composition;

// The VendPaymProposalAutomationOccurrenceDeleteProvider class is designed to handle
// deleting the appropriate VendPaymProposalAutomationCriteria records when ProcessScheduleOccurrence
// records are deleted.
[ExportMetadata(extendedTypeStr(ProcessScheduleTypeName), 'VendPaymProposalAutomation')]
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleIDeleteOccurrence))]
internal final class VendPaymProposalAutomationOccurrenceDeleteProvider
    implements ProcessScheduleIDeleteOccurrence
{
    private ProcessScheduleSeriesOccurrenceTmp occurrencesExplodedTmp;

    [Wrappable(false)]
    public void deleteOccurrences(ProcessScheduleSeriesOccurrenceTmp _occurrencesExplodedTmp)
    {
        this.initialize(_occurrencesExplodedTmp);
        this.deleteVendPaymProposalAutomationCriteria();
    }

    private void initialize(ProcessScheduleSeriesOccurrenceTmp _occurrencesExplodedTmp)
    {
        occurrencesExplodedTmp.linkPhysicalTableInstance(_occurrencesExplodedTmp);
    }

    private void deleteVendPaymProposalAutomationCriteria()
    {
        VendPaymProposalAutomationCriteria automationCriteria;
        automationCriteria.skipDeleteActions(true);
        automationCriteria.skipDataMethods(true);
        automationCriteria.skipAosValidation(true);
        automationCriteria.skipDatabaseLog(true);
        automationCriteria.skipEvents(true);
        delete from automationCriteria
            exists join occurrencesExplodedTmp
            where automationCriteria.ProcessScheduleOccurrence ==
                occurrencesExplodedTmp.ProcessScheduleOccurrence;
    }
}

ProcessScheduleIDeleteSeries interface

The ProcessScheduleIDeleteSeries interface resembles ProcessScheduleIDeleteOccurrence. The event is
invoked whenever a series is deleted. You should delete all parameter records for all occurrences. These records
include the series template record.

A SQL Database temp table is passed in so that you can do set-based deletes.
using System.ComponentModel.Composition;

// The VendPaymProposalAutomationSeriesDeleteProvider class is designed to handle
// deleting the appropriate VendPaymProposalAutomationCriteria records when ProcessScheduleSeries records are deleted.
[ExportMetadata(extendedTypeStr(ProcessScheduleTypeName), 'VendPaymProposalAutomation')]
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleIDeleteSeries))]
internal final class VendPaymProposalAutomationSeriesDeleteProvider
    implements ProcessScheduleIDeleteSeries
{

    [Wrappable(false)]
    public void deleteSeries(RefRecId _seriesRecId)
    {
        this.deleteVendPaymProposalAutomationCriteria(_seriesRecId);
    }

    private void deleteVendPaymProposalAutomationCriteria(RefRecId _seriesRecId)
    {
        VendPaymProposalAutomationCriteria automationCriteria;
        automationCriteria.skipDeleteActions(true);
        automationCriteria.skipDataMethods(true);
        automationCriteria.skipAosValidation(true);
        automationCriteria.skipDatabaseLog(true);
        automationCriteria.skipEvents(true);

        delete_from automationCriteria
        where automationCriteria.ProcessScheduleSeries == _seriesRecId;
    }
}

ProcessScheduleIExplodeOccurrences interface

When a user creates a new series through the UI, all the future occurrences are generated. Therefore, if the
series runs every day, the process automation framework creates an occurrence for every day. This action is
known as generating the series. The ProcessScheduleIExplodeOccurrences event is fired when the series is
generated. The series template record should be used as a template to create parameter records for each
occurrence in the parameter tables.

A SQL Database temp table is passed in so that you can do set-based creation of parameter records for optimal
performance.

In the following example, a parameter table stores a single parameter that is named Type. This parameter isn't
related to the process automation framework type but is specific to cash flow forecasting.
using System.ComponentModel.Composition;

// Provider for cash flow forecast automation generate occurrences.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleIExplodeOccurrences))]
[ExportMetadata(extendedTypeStr(ProcessScheduleTypeName), 'LedgerCovTotalProcessAutomation')]
internal final class LedgerCovTotalProcessAutomationExplodeOccurrencesProvider
    implements ProcessScheduleIEplodeOccurrences
{
    private void new()
    {
    }

    [Wrappable(false)]
    public void explodeOccurrences(ProcessScheduleSeriesOccurrenceTmp _occurrencesExplodedTmp)
    {
        LedgerCovTotalProcessAutomationSchedulingParameters parameters;
        LedgerCovTotalProcessAutomationSchedulingParameters
            parametersSeriesRecord;

        insert_recordset parameters
        {
            Type,
            ProcessScheduleSeries,
            ProcessScheduleOccurrence
        }

        select Type, ProcessScheduleSeries from parametersSeriesRecord
            where parametersSeriesRecord.ProcessScheduleOccurrence == 0
            join ProcessScheduleOccurrence from _occurrencesExplodedTmp
            where _occurrencesExplodedTmp.ProcessScheduleSeries ==
            parametersSeriesRecord.ProcessScheduleSeries
                && _occurrencesExplodedTmp.TypeName ==
                LedgerCovTotalProcessAutomationConstants::RegisteredTypeName;
    }
}
This topic describes how to create configurable queries and use them with the process automation framework. If a process won't support user-configurable queries via the `SysQueryForm` form, you can skip this task.

The process automation framework provides limited support for custom queries via the `SysQueryForm` form. A custom query lets a user add custom criteria to limit how a process runs. The framework has logic to extract user-provided custom criteria and tables to store those criteria. The custom query criteria are stored for each occurrence of a given series and can be modified individually. The framework also provides an API to apply the custom criteria to the query that is used to run the process for each occurrence.

**NOTE**

When a user applies query criteria, the whole query object isn't saved. Instead the query criteria are saved individually, to allow for better support of query extensions. Therefore, extensions that are made to existing queries for existing query criteria should not cause breaking changes when this approach is used. In this case, a new extension should not require modification or re-creation of the query criteria for a saved series or occurrences. However, modification or re-creation of the query criteria is allowed.

### ProcessScheduleIQueryable interface

The `ProcessScheduleIQueryable` interface retrieves the original query (that is, the query as it was before the user modified it) and the user-modified query. These queries are used either to apply criteria when the process runs or to extract criteria when the user makes changes. These criteria are stored by the process automation framework.

This interface is accessed in the criteria form for a given implementation of process automation. For an example of access to this interface, see the `VendPaymProposalAutomationCriteria` form. That form also has a sample implementation of the `SysQueryForm` form.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>public Query getOriginalQuery()</code></td>
<td>This method gets the original, unmodified query to use as a basis for comparison.</td>
</tr>
<tr>
<td><code>public QuerygetQueryForApplicationOrExtractionOfQueryCriteria()</code></td>
<td>This method gets the query that has been or will be modified, and that is used to apply or extract query criteria.</td>
</tr>
</tbody>
</table>

**NOTE**

The query that is used on the implementation of `ProcessScheduleIQueryable` must have the same structure as the query that is used during the run of the underlying process that is being automated. Any structural deviation that isn't additive in nature will cause runtime errors when the saved query criteria are applied at runtime. To ensure that the query structure remains the same, you should either use a designed query or use shared logic that builds up the query.

### ProcessScheduleQueryCriteriaApplicator class

The `ProcessScheduleQueryCriteriaApplicator` class is used to apply the saved query criteria for a given occurrence to the runtime instance of the query that is used when a process is run. This API must be called by an
uptaking process at a point in the run where the query is ready to accept the saved criteria. If a designed query or shared logic that builds up the query is used, this call can typically occur after the query has been correctly initialized. For an example that shows how this API is used, see the `CustVendCreatePaymJournal.constructFromAutomationExecutionContract` method.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public static void applyCriteriaForOccurrenceExecution(Query _queryToApplyCriteria, RefRecId _scheduleOccurrenceRecId)</td>
<td></td>
</tr>
</tbody>
</table>
To run in the process automation framework, a process must implement the `ProcessAutomationTask` interface. The framework uses this interface to provide an instance of `ProcessScheduleWorkItem`. That instance contains information about the series, the occurrence that is being run (if applicable), and the execution ID. You must create the batch task that has to be run, and you must provide the task to the framework. The framework then creates the batch header and the tasks that are provided.

Polled processes don't have occurrences, because they might be run frequently, and those frequent runs will create many more occurrences than you want to track. Instead, you use a unique execution ID to track every run of a polled process. An execution ID is also assigned to scheduled processes.

The `getListOfWorkToBePerformed` method determines whether there is work that must be done. If there is, the method returns a list of batch-enabled classes that inherit from `SysOperationServiceController`. This method must be efficient and fast, because it's run in the context of the polling process. Therefore, you should not do any work in this method except check whether work must be done and create batch tasks for any work that must be done. It's OK if the method returns an empty list, because an empty list indicates that no work must be done. In this case, the process automation framework doesn't create any batch processes.

The process automation framework supports a list for those processes that do parallel processing and that want multiple batch tasks. If the process that is being run is an older process that implements `RunBaseBatch`, it can't be returned through the list. In this case, you have two options:

- Convert the process to `SysOperationServiceController`. For more information, see [SysOperations Framework](#). This option is recommended, if it's feasible.

- Wrap the legacy `RunBaseBatch` class with a new class that inherits from `SysOperationServiceController`. For an example, see [LedgerCovTotalProcessAutomationProcessor](#) in the Application Object Tree (AOT).

The following example shows an implementation of the `ProcessAutomationTask` interface.
using System.ComponentModel.Composition;

// The test class to test the process automation task engine.
[ExportMetadataAttribute(classStr(ProcessAutomationTask),
classStr(ProcessAutomationTaskTestImplementation))]
[ExportAttribute(identifierStr('Microsoft.Dynamics.AX.Application.ProcessAutomationTask'))]
internal final class ProcessAutomationTaskTestImplementation extends ProcessAutomationTask
{
    protected boolean isProcessAutomationEnabledForThisTask()
    {
        return true;
    }

    protected List getListOfWorkToBePerformed()
    {
        ProcessScheduleWorkItem scheduleWorkItemToExecute = this.parmProcessScheduleWorkItem();
        List taskList = new List(Types::Class);
        ProcessAutomationTestProcess testProcess = ProcessAutomationTestProcess::construct(scheduleWorkItemToExecute);
        taskList.addEnd(testProcess);
        return taskList;
    }

    // Gets and sets the batch job caption that will be used by the batch job scheduled to run this process.
    // Returns the batch caption that will be used for the batch job that will perform the task.
    protected BatchCaption batchJobCaption()
    {
    }
}

ProcessScheduleWorkItem class

The ProcessScheduleWorkItem class has many pieces of information and is designed to represent a process that must be run.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public ProcessExecutionId parmExecutionId(ProcessExecutionId _executionId = executionId)</td>
<td>The execution ID is used to log errors. A polled process gets a new, unique execution ID every time that it's run. Because scheduled processes are only ever run one time for each occurrence, each occurrence only ever has one execution ID.</td>
</tr>
<tr>
<td>public RefRecId parmProcessScheduleOccurrenceRecId(RefRecId _scheduleOccurrenceRecId = scheduleOccurrenceRecId)</td>
<td>The occurrence that is being run. Use this method to reference occurrence-specific parameter information in parameter tables. Polled processes don't have a RecId value for an occurrence.</td>
</tr>
<tr>
<td>public RefRecId parmProcessScheduleSeriesPatternRecId(RefRecId _scheduleSeriesPatternRecId = scheduleSeriesPatternRecId)</td>
<td>The series pattern that the process is associated with. Currently, series can have only one pattern. All parameter records typically have a foreign key to this pattern.</td>
</tr>
<tr>
<td>public ProcessScheduleProcessType parmProcessScheduleType(ProcessScheduleProcessType _scheduleType = scheduleType)</td>
<td>The schedule type of the process: polled or scheduled.</td>
</tr>
<tr>
<td>public ProcessScheduleTypeName parmProcessScheduleTypeName(ProcessScheduleTypeName _scheduleTypeName = scheduleTypeName)</td>
<td>The type name that the process and series are associated with, such as VendPaymentProposal. This name is an internal developer name and isn't shown to the user.</td>

<td>DESCRIPTION</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>public List parmLegalEntityList(List _legalEntityList = legalEntityList)</td>
<td>The list of legal entities that the process will be run against. If the process is a global process, this list will be null. If the process is run against a single company, this list will contain a single company. Multiple companies aren't currently supported, but they might be supported in the future.</td>
</tr>
<tr>
<td>public Name getName()</td>
<td>Returns the occurrence name. If a type is polled, this method returns the series name.</td>
</tr>
<tr>
<td>public ProcessScheduleSeriesName parmSeriesName(ProcessScheduleSeriesName _seriesName = seriesName)</td>
<td>The name of the series.</td>
</tr>
<tr>
<td>public Name parmOccurrenceName(Name _occurrenceName = occurrenceName)</td>
<td>The occurrence name. If the process is a polled process, the value will be empty.</td>
</tr>
<tr>
<td>public List parmTaskList(List _taskList = taskList)</td>
<td>The list of batch tasks that the process automation framework should add to the batch. If this list is null, it's assumed that no work must be done, and nothing will be created in a batch.</td>
</tr>
<tr>
<td>public ProcessScheduleDateTime parmScheduledDateTime(ProcessScheduleDateTime _scheduledDateTime = scheduledDateTime)</td>
<td>The date and time when the process was scheduled to run. This date and time might differ from the actual date and time when the process runs.</td>
</tr>
<tr>
<td>public UserGroupId parmOwnerId(UserGroupId _ownerId = ownerId)</td>
<td>The owner of the occurrence that is being run.</td>
</tr>
<tr>
<td>public void initializeFromScheduleWorkItem(ProcessScheduleWorkItem _item)</td>
<td>Initializes an instance of ProcessScheduleWorkItem from another instance.</td>
</tr>
</tbody>
</table>
The process automation framework supports logging of results and messages. There are two reasons why a process should log results and messages:

- Results and the message log communicate the state of a process to the system admin or other roles that have access. It’s important that process results be monitored and seen by someone. If failures occur, they can be fixed, or an issue can be raised with the process owner.
- Results should communicate what the process did. For example, if the process posts vendor invoices, the results can show all the vendor invoices. In this case, each result will show the status and a link to the vendor invoice.

Results and messages are a multilevel logging system. A process has one or more results. Each result has one or more messages that are specific to it. A message is a composition child of the result. A result is typically something that the process is processing. For example, if the process posts vendor invoices, you log each vendor invoice as a result. Then, for each posting of each vendor invoice, you can log multiple messages that are associated with that result. If a vendor invoice is successfully posted, it’s OK to leave the message log blank, because the success of the operation should be obvious when users look at the result. If warnings occur, you should write them to the message log, even if posting was successful. These messages provide transparency, so that users can see what each process is doing and what the results are.

Both scheduled processes and polled processes support logging of results and messages. All processes should create a result. At a minimum, the result should communicate the fact that everything was successful. Processes that do work that affects user work and is visible to users should create more detailed results. For the vendor invoice posting example that was used earlier, users might want to see that their invoices have been posted. Results that don’t show that information can cause confusion, even if the information is available in other ways.

The following illustration shows the result view.

The following illustration shows the message view. To open this view, select View log in the Log column in the result view.
ProcessExecutionSourceLink table

The ProcessExecutionSourceLink table contains the results that are created while the processing is running. This table contains RefTableId and RefRecId fields. These fields are links to any source record in Microsoft SQL Server and are typically something that the process is processing. This table also contains Header and Message fields. The Header field will be shown as a column in the result grid. The message can be anything that you want it to be.

For example, if vendor payment proposal is creating a payment journal, the RefTableId value is the table ID of the LedgerJournalTable table. The RefRecId value is the RecId value of the LedgerJournalTable record that the payment journal created by the running process. In this case, you can set the Header field to the journal number. You can even make this value a jump reference, so that users can select the journal number to go directly to the payment journal. You can set the Message field to any message that you want to show, such as Payment journal created successfully.

If the process is processing many items (for example, if it’s posting many invoices), you can create a ProcessExecutionSourceLink record for each invoice. If the number of items that the process is processing is very large (in the millions), and users don’t have to see the details of each item, consider summarizing the items into batches. For example, the process for subledger transfer to the general ledger creates a ProcessExecutionSourceLink record for each transfer ID that is transferred to the general ledger, not for each voucher that is transferred.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public static void insertSourceLinks(ProcessScheduleTypeName _typeName, ProcessExecutionSourceLinkTmp _tmp)</td>
<td>This method is new in version 10.0.14. It inserts many results into the ProcessExecutionSourceLink table by using set-based insert.</td>
</tr>
<tr>
<td>public static ProcessExecutionSourceLink insertSourceLink(ProcessExecutionSourceLinkItem _sourceLinkItem)</td>
<td>This method inserts a record into the ProcessExecutionSourceLink table.</td>
</tr>
</tbody>
</table>

ProcessExecutionSourceLinkItem class

Instantiate the ProcessExecutionSourceLinkItem class, and fill it with values that are required to correctly show your source item.
<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
</table>
| public static ProcessExecutionSourceLinkItem newFromProcessScheduleWorkItemAndStatus(ProcessScheduleWorkItem _workItem, ProcessExecutionSourceStatus _status) | Use this constructor to create an instance of `ProcessExecutionSourceLinkItem`. This method correctly initializes many of the required fields from `ProcessScheduleWorkItem`.
| public static ProcessExecutionSourceLinkItem newFromProcessExecutionSourceLink(RefRecId _processExecutionSourceLinkRecId) | This method constructs an instance of `ProcessExecutionSourceLinkItem` and initializes the instance by using the specified record ID of a `ProcessExecutionSourceLink` record.
| public RefRecId parmSourceRecId(RefRecId _sourceRecId = sourceRecId) | Set the record ID of the source record. For example, this value might be the record ID of the vendor invoice header table.
| public RefTableId parmSourceTableId(RefTableId _sourceTableId = sourceTableId) | Set the table ID of the source table. For example, this value might be the table ID of the vendor invoice header table.
| public ProcessExecutionSourceLinkHeader parmHeader(ProcessExecutionSourceLinkHeader _header = header) | Set the value for the header field. For the vendor invoice posting example that was used earlier, this value might be the invoice number.
| public ProcessExecutionSourceLinkMessage parmMessage(ProcessExecutionSourceLinkMessage _message = message) | Set the message. For the vendor invoice posting example that was used earlier, this value might be **Posting successful**.
| public ProcessExecutionId parmExecutionId(ProcessExecutionId _executionId = executionId) | This method sets the execution ID. This value was provided via `ProcessScheduleWorkItem` in the implementation of the `ProcessAutomationTask` interface.

**ProcessExecutionMessageLog table**

The `ProcessExecutionMessageLog` table contains messages that are related to a single `ProcessExecutionSourceLink` record. You can write any type of message to this table. The message will then be shown to users.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
</table>
| public static void insertMessages(ProcessScheduleTypeName _typeName, ProcessExecutionMessageLogTmp _tmp) | This method inserts messages into the `ProcessExecutionMessageLog` table by using a set-based insert.
| public static ProcessExecutionMessageLog insertMessage(ProcessExecutionMessageLogItem _errorLogItem) | This method inserts a message into the message log.

**ProcessExecutionMessageLogItem class**

The message log stores messages as both strings and label IDs. You don’t have to set both values. Label IDs are preferred, because they support translation of messages in the user interface (UI) for the message log. However, the messages are provided for backward compatibility with processes that don't support logging of label IDs.

Use the appropriate constructor for your scenario.
<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public static ProcessExecutionMessageLogItem newFromProcessExecutionSourceLinkAndMessage(RefRecId _processExecutionSourceLinkRecId, Exception _exception, ProcessExecutionMessage _message)</td>
<td></td>
</tr>
<tr>
<td>public static ProcessExecutionMessageLogItem newFromProcessExecutionSourceLinkAndLabel(RefRecId _processExecutionSourceLinkRecId, Exception _exception, LabelId _labelId, container _labelParameters)</td>
<td></td>
</tr>
</tbody>
</table>
The process automation framework supports some customizations of the user interface (UI). Most of this topic is optional, because the framework provides default values for everything. The only exception is the `ProcessScheduleSeries` form. If you intend to show the `ProcessScheduleSeries` form for a specific product area, customizations are required so that the framework can show data that is specific to that product area.

**Weekly calendar view**

**ProcessScheduleIBuildOccurrenceCard interface**

The `ProcessScheduleIBuildOccurrenceCard` interface lets you customize the appearance of occurrence cards in the weekly calendar view. There is a static method on the interface for each status of an occurrence: `Scheduled`, `Waiting`, `Running`, `Successful`, `Failed`, and `Disabled`. You can create a customized occurrence card for each status value. Each of these methods returns an instance of `ProcessScheduleOccurrenceCard`.

The process automation framework provides a default implementation in the `ProcessScheduleOccurrenceCardBuilder` class. You inherit from this class and override the functionality as you require. You then register your derived class via the `SysPlugin` for your specific type. The registration process resembles the process for many of the plug-ins in the framework documentation.

An instance of `ProcessScheduleOccurrenceCardBuilderContract` is passed into each of the methods and can be used to retrieve information about the occurrence. The derived class can invoke the default implementation for each static method that returns the `ProcessScheduleOccurrenceCard` instance, modify whatever is required, and return it.

**ProcessScheduleOccurrenceCard class**

The `ProcessScheduleOccurrenceCard` class lets you customize the appearance of an occurrence card that is shown in the calendar view. The first two lines are controlled by the process automation framework and can’t be modified. In the following illustration, the subheader is the `Completed at` phrase, and the status message is the word `Completed` that has a blue background.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>public str parmSubHeader(str _subHeader = cardSubHeader)</code></td>
<td>The subheader, which is the third line of the occurrence card that is shown in the previous illustration.</td>
</tr>
</tbody>
</table>
### public str parmStatusMessage(str _statusMessage = statusMessage)
- The status message, which represents the status of the process and has a colored background.

### public ProcessExecutionOccurrenceCardStatusColor parmStatusColor(ProcessExecutionOccurrenceCardStatusColor _statusColor = statusColor)
- The color of the background for the status message.

### ProcessScheduleIShowOccurrenceCalendarView interface
The `ProcessScheduleIShowOccurrenceCalendarView` interface must be implemented by forms that will show the weekly calendar view. The `ProcessScheduleSeries` form is an example of a form that implements this interface.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ProcessScheduleOccurrenceCalendarViewContract getProcessScheduleOccurrenceCalendarViewContract()</td>
<td>Return the contract that the weekly view will use to determine which types should be shown.</td>
</tr>
<tr>
<td>void refreshAfterChangeToCalendarView()</td>
<td>This value is a callback from the weekly view. It indicates that the parent form should be refreshed because of changes in the weekly calendar view.</td>
</tr>
</tbody>
</table>

### ProcessScheduleOccurrenceCalendarViewContract class
Use the `ProcessScheduleOccurrenceCalendarViewContract` class to limit the series that the weekly calendar view should show. For an example, see `ProcessScheduleSeries.getProcessScheduleOccurrenceCalendarViewcontract` in the Application Object Tree (AOT).

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public static ProcessScheduleOccurrenceCalendarViewContract construct()</td>
<td>Use this constructor if the intention is to show occurrences for one to many types.</td>
</tr>
<tr>
<td>internal static ProcessScheduleOccurrenceCalendarViewContract newFromScheduleSeries(ProcessScheduleSeries _scheduleSeries)</td>
<td>Use this constructor if the intention is to show occurrences for a single series.</td>
</tr>
<tr>
<td>public void AddScheduleType(ProcessScheduleTypeName _scheduleTypeName)</td>
<td>If you aren't showing just one series, use this value to add the types that should be shown.</td>
</tr>
</tbody>
</table>

### ProcessScheduleOccurrenceCalendarViewRenderer class
Use the `ProcessScheduleOccurrenceCalendarViewRenderer` class to render the weekly calendar view in an existing form. A form part will be created and correctly initialized. An example of this class is used in the `ProcessScheduleSeries` form.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public static ProcessScheduleICalendarView renderCalendarViewInFormControl(FormGroupControl _containingGroupControl)</td>
<td>This method renders the weekly calendar view in the specified form group control.</td>
</tr>
</tbody>
</table>

### Render interfaces
Several interfaces enable customization of the way that occurrence processes are rendered in the calendar view.
There is one interface for each status that a process can have:

- ProcessScheduleIRenderDisabledOccurrenceCard
- ProcessScheduleIRenderFailedOccurrenceCard
- ProcessScheduleIRenderRunningOccurrenceCard
- ProcessScheduleIRenderScheduledOccurrenceCard
- ProcessScheduleIRenderSuccessfulOccurrenceCard
- ProcessScheduleIRenderWaitingOccurrenceCard

All these interfaces follow the same pattern. An instance of ProcessScheduleOccurrenceCardRendering is sent to them. That instance is used to control how the occurrence card is rendered.

For an example, see the CustVendPaymProposalAutomationOccurrenceCardRenderer class in the AOT.

**ProcessScheduleOccurrenceCardRendering class**

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public ProcessScheduleOccurrence getOccurrenceBeingRendered()</td>
<td>This method returns the occurrence that is being rendered on the occurrence card.</td>
</tr>
<tr>
<td>public ProcessExecutionExecutingInformation getOccurrenceExecutionInformation()</td>
<td>This method returns the running information for the occurrence. This information typically includes the results of the batch job, the start time, and the end time.</td>
</tr>
<tr>
<td>public void makeCardSubHeaderInvisible()</td>
<td>This method makes the card's subheader invisible. See the illustration earlier in this topic and the content below it to determine which line is the subheader.</td>
</tr>
<tr>
<td>public void makeCardButtonsInvisible()</td>
<td>This method specifies whether the Disable and Edit buttons on the occurrence card are invisible.</td>
</tr>
<tr>
<td>public void setColumnsOnOccurrenceCardDetailGroup(int _numberOfColumns)</td>
<td>This method enables the number of columns on the occurrence card to be customized. By default, there are two columns.</td>
</tr>
<tr>
<td>public FormButtonControl addButtonControl(FormControlName _buttonControlName)</td>
<td>This method enables a new button to be added to the occurrence card.</td>
</tr>
<tr>
<td>public FormStaticTextControl addStaticTextControl(FormControlName _staticTextControlName)</td>
<td>This method enables a static text control to be added to the occurrence card.</td>
</tr>
<tr>
<td>public FormStringControl addStringControl(FormControlName _stringControlName, LabelId _stringControlLabel)</td>
<td>This method adds a string control to the occurrence card.</td>
</tr>
</tbody>
</table>

**Series list page**

**ProcessScheduleISeriesFormController interface**

The Series list page uses the ProcessScheduleISeriesFormController controller to determine which types series will be shown for on the ProcessScheduleSeries list page. This class uses the SysPlugIn class. The menu item that you use to open the ProcessScheduleSeries form is used as the key to invoke the specified plug-in. This key enables each use of this form to customize which types are shown.
// Implementation of the ProcessScheduleISeriesFormController for the admin view of the process schedule Series form.
// This implementation will show series for all process types, both scheduled and polled, on the Series form.
[Export(identifierStr(Dynamics.AX.Application.ProcessScheduleISeriesFormController))]
[ExportMetadata(classStr(ProcessScheduleISeriesFormController), menuItemDisplayStr(ProcessScheduleSeriesAdmin))]
internal class ProcessScheduleSeriesFormAdminController implements ProcessScheduleISeriesFormController
{
    [Hookable(false)]
    public ProcessScheduleSeriesFormContract getSeriesFormContract()
    {
        return ProcessScheduleSeriesFormContract::newForAllScheduleTypes();
    }
}

**ProcessScheduleSeriesFormContract class**

The **ProcessScheduleSeriesFormContract** class is a contract that the series list page uses to determine which **ProcessScheduleType** is shown on it. This class can be used in a workspace to show series only for specific types that are related to that workspace.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>public void addScheduledScheduleType(ProcessScheduleTypeName _scheduleTypeName)</td>
<td>Add a specific scheduled type.</td>
</tr>
<tr>
<td>public void addPolledScheduleType(ProcessScheduleTypeName _scheduleTypeName)</td>
<td>Add a specific polled type.</td>
</tr>
</tbody>
</table>

**Results and messages**

**ProcessExecutionIResultsController interface**

The **ProcessExecutionIResultsController** interface lets you customize the results dialog box according to your process. It lets you set the column header label for the **Header** field in the results grid and make the value in the header column a hyperlink. This interface should be implemented by a class that is a plug-in. Here is a sample plug-in.
using System.ComponentModel.Composition;

[Export(identifierStr(Dynamics.AX.Application.ProcessExecutionResultsController))]
[ExportMetadata(classStr(ProcessExecutionResultsController), 'TestScheduledType')]
public final class ProcessExecutionSampleUptakeExecutionResultsController implements
ProcessExecutionIResultsController
{
    [Hookable(false)]
    public ProcessExecutionResultsDialogContract getResultsDialogContract()
    {
        ProcessExecutionResultsDialogContract contract = ProcessExecutionResultsDialogContract::construct();
        contract.parmSourceLinkHeaderLabel('Sample Header');
        contract.parmShouldSourceLinkHeaderBeLinkToSourceLinkDetails(true);
        return contract;
    }

    [Hookable(false)]
    public void openSourceLinkDetails(RefTableId _refTableId, RefRecId _refRecId)
    {
        if (_refTableId == tableNum(SystemParameters))
        {
            Args args = new Args();
            MenuFunction systemParametersMenuFunction = new
            MenuFunction(menuItemDisplayStr(SystemParameters), MenuItemType::Display);
            systemParametersMenuFunction.run(args);
        }
    }
}

### ProcessExecutionResultsDialogContract class

The **ProcessExecutionResultsDialogContract** class lets you customize the header column label and specify whether the data in the header column should be rendered as a hyperlink.

### ProcessExecutionMessageLogDialog class

The **ProcessExecutionMessageLogDialog** interface enables the message log to be opened in the context of something from the source domain. For example, the message log can be opened from the page for a posted vendor invoice to show the messages that were logged while the vendor invoice was being posted by a process that is enabled for the process automation framework. For this example, the posted vendor invoice page must
implement the `ProcessExecutionMessageLogDialog` interface. By using this interface, you don't have to build your own private results/messaging subsystems.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getContractForMessageLog()</code></td>
<td>This method returns an instance of <code>ProcessExecutionMessageLogContract</code>.</td>
</tr>
</tbody>
</table>

**ProcessExecutionMessageLogContract class**

The `ProcessExecutionMessageLogContract` contract lets you limit the message log to a specific item from the source domain. In the `ProcessExecutionSourceLink` table, there must be a record where the `RefRecId` and `RefTableId` values match the values that the contract sends.

<table>
<thead>
<tr>
<th>METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>newForSourceRecord(ProcessScheduleTypeName _typeName, RefTableId _refTableId, RefRecId _refRecId, guid _executionId = emptyGuid())</code></td>
<td>This method initializes the contract by using the specified type name, <code>RefTableId</code> value, and <code>RefRecId</code> value. There should be a matching record in the <code>ProcessExecutionSourceLink</code> table. Background processes will have multiple execution IDs. Therefore, the optional parameter for the execution ID should be provided for background processes. For more information, see <a href="#">Type registration</a>.</td>
</tr>
</tbody>
</table>
The Regression suite automation tool (RSAT) significantly reduces the time and cost of user acceptance testing (UAT) of Finance and Operations apps. UAT is typically required before you take a Microsoft application update, or before you apply custom code and configurations to your production environment. RSAT lets functional power users record business tasks by using Task recorder and then convert the recordings into a suite of automated tests, without having to write source code. For more information about Task recorder, see Task recorder resources.

RSAT is fully integrated with Microsoft Azure DevOps for test execution, reporting, and investigation. Test parameters are decoupled from test steps and stored in Microsoft Excel files.

RSAT usage is described in these topics:

- Regression Suite Automation Tool (this topic)
- Regression Suite Automation Tool installation and configuration
- Run Regression Suite Automation Tool test cases
- Maintain test cases withinRegression suite automation tool
- Validate expected values
- Chain test cases
- Derived test cases
- Configure non-administrator users to use RSAT
- Upgrade the parameter files
- Regression Suite Automation Tool best practices
- Troubleshoot the Regression Suite Automation Tool

**Getting started videos**

These videos will help introduce RSAT and get you started.

**Use task recorder to create a test case for RSAT**

The How to use task recorder to create a test case for the Regression suite automation tool (RSAT) video (shown above) is included in the Finance and Operations playlist available on YouTube.

**Create a test plan in Azure DevOps to use with RSAT**

The How to create a test plan in Azure DevOps to use with the Regression suite automation tool (RSAT) video (shown above) is included in the Finance and Operations playlist available on YouTube.

**How to use RSAT**

The How to use the Regression suite automation tool (RSAT) video (shown above) is included in the Finance and Operations playlist available on YouTube.

**The improved Excel experience in RSAT 2.0**

The Improved Excel experience in RSAT 2.0 video (shown above) is included in the Finance and Operations playlist available on YouTube.
End-to-end flow

RSAT is part of the end-to-end flow described below. RSAT, Microsoft Dynamics Lifecycle Services (LCS), and Azure DevOps provide a set of tools for test case authoring (using Task recorder), distribution, configuration, execution, investigation, and reporting.

To learn more about this process, see [Create and automate user acceptance tests](#).

LCS, BPM, and Task Recordings

You aren't required to use the Business process modeler (BPM) tool in LCS. BPM is recommended if you want to enable the management and distribution of test libraries across projects and tenants. These capabilities are especially useful for Microsoft partners and independent software vendors (ISVs). BPM enables the distribution of test libraries as part of LCS solutions.

If you are not using BPM, you can manually create test cases in Azure DevOps and attach developer recording files to your Azure DevOps test cases. You can create developer recording files directly from the Task recorder pane.
You must name the developer recording file `Recording.xml` before attaching it to the Azure DevOps test case. Alternatively, you can name the recording file `-Test Case Title-.xml`, where `-Test Case Title-` is the DevOps title of the test case.

**Intended usage and test classification**

**Business cycle (business process) testing**

The Regression suite automation tool is intended to be used for business cycle tests and scenario tests (multiple component tests) that usually occur at the end of the development lifecycle. This is also referred to as user acceptance testing. Business cycle testing consists of a smaller number of test cases than component or unit testing. This is illustrated in the following graphic.

**Cloud POS**

In addition to testing processes recorded using the Finance and Operations Task recorder, RSAT also supports...
testing of Cloud POS processes in Dynamics 365 Commerce. For more information about RSAT with Cloud POS, see Test recorder and Regression suite automation tool for Cloud POS.

**Warehouse mobile app**
You can use RSAT in combination with the Warehouse App Task Validation Framework to automate the testing of warehouse processes. This Tech Talk is a good reference to get started.

**Unit and component testing**
For unit tests, we do not recommend that you use RSAT. Instead, use the SysTest framework and the build/test automation tools. For component tests, take advantage of the Acceptance test library resources (ATL). ATL is a library of X++ test helpers. When used with the SysTest framework, it offers the following benefits:

- Lets you create consistent test data.
- Increases the readability of test code.
- Provides improved discoverability of the methods that are used to create test data.
- Hides the complexity of setting up prerequisites.
- Supports high performance of test cases.

For more details, see Continuous delivery home page.

**Data integration testing**
Do not use RSAT for integration tests, instead rely on the data management framework (also known as DIXF). The Data task automation framework enables you to configure and automate the testing of your data integration scenarios.

**RSAT User interface overview**
RSAT 2.1 introduced a modern user interface that simplifies navigation through the main components of the app, including a Quick links tab, and quick navigation to DevOps test suites and test runs.

Use the left navigation pane to navigate between the test plan, settings, Cloud POS settings and the quick links page.

**Test Plan**
The Test plan tab is the main tab that allows you to interact with and execute test cases.

**Settings**
Select the Settings tab to configure RSAT settings. Use the top bar to navigate between general, optional and process settings. You do not need to save your settings, settings are automatically saved as soon as you navigate out of the settings page. You can also save your settings in an RSAT settings file or open an existing settings file.
Cloud POS Settings

Select the Cloud POS Settings tab to configure RSAT to execute Cloud POS test cases. You do not need to save your settings, settings will automatically be saved as soon as you navigate out of the settings page.

Useful links

The Links tab provides new functionality. Select the Links tab to quickly navigate to your Finance and Operations environment, Cloud POS, or go to useful Azure DevOps pages showing recent test runs, the last test run, and current test plan. There is also a link to the RSAT docs page.
Quick navigation to Azure DevOps

When working with your test plan, the **Open** button now provides 3 options.

- Open the selected test case in Azure DevOps.
- Open the selected test suite.
- Open the recent test runs.

This tab provides quick access to the most relevant pages in Azure DevOps.
This topic contains information about how to install and configure the Regression suite automation tool (RSAT).

**Prerequisites**

**Test environment (Prerequisite)**

Your test environment must be running Platform update 15 or newer. The Regression suite automation tool must have access to your test environment via a web browser.

**Excel**

You need Microsoft Excel installed to generate and edit test parameters.

**Azure DevOps (Prerequisite)**

You must have an Azure DevOps project to store and manage your test cases, test plans, and test case results. You will need an Azure DevOps Test Manager or Test Plans license. For example, if you have a Visual Studio Enterprise subscription, you already have a license to Test Plans. For more information, see Pricing for Azure DevOps Services or Pricing for Azure DevOps Server.

**Authentication Certificate**

RSAT is designed to be installed on any Windows 10 computer and connect remotely via a web browser to an environment.

To enable secure authentication, RSAT requires a certificate to be installed on the RSAT client computer. The RSAT settings dialog box allows you to automatically create and install the authentication certificate. You will also need to configure the virtual machine (VM) to trust the connection. Follow the instructions in the next sections to install and configure RSAT.

**Installation**

**Installer**

Download the .msi file from the Regression Suite Automation Tool Download to your machine and double-click it to run the installer.
NOTE
If you're using Azure DevOps Server, download and install version 1.210.48249.4 or later.

Selenium and Browser Drivers
RSAT requires Selenium and web browser driver libraries. RSAT will prompt you if needed libraries are missing and will automatically install them for you. Select Yes when you see the following (or similar) messages.

RSAT uses Selenium 3.13.1. The web driver library and browser-specific drivers are downloaded to C:\Program Files (x86)\Regression Suite Automation Tool\Common\External\Selenium.

Configuration
1. Open RSAT from your desktop.

2. Select the Settings tab on the upper left to configure RSAT.
General settings

These settings are required.

**Azure DevOps (General settings)**

Configure your connection to the Azure DevOps project and test plan.

- **Azure DevOps URL** - This is the URL of your Azure DevOps organization. For example, https://yourAzureDevOpsUrlHere.visualStudio.com.

  **NOTE**

  If you're using Azure DevOps Server, add /DefaultCollection to the end of your Azure DevOps URL.

- **Access Token** - The access token that allows the tool to connect to Azure DevOps. You need to create a personal access token or use an existing one that you have saved. It is recommended you create this with scope selected as Full Access. For more information, see Authenticate access with personal access tokens.

- **Project Name** - The name of your Azure DevOps project. RSAT will automatically detect project names and test plans available based the Azure DevOps URL specified. You can then select the Test Project and Test Plan.

- **Test Plan** - The Azure DevOps test plan that contains your test cases. For more information, see Create test plans and test suites.

Select Test Connection to test your connection to Azure DevOps.

**Test environment (General settings)**

Configure your connection to the test environment.
- **Hostname** – The hostname of the test environment, such as myhost.cloudax.dynamics.com. Don't include the https:// or http:// prefix.

- **SOAP Hostname** – The SOAP hostname of the test environment.
  - For demo and development environments (also known as one-box environments), add a `soap` suffix to the hostname. For example, if your hostname is `myhost.cloudax.dynamics.com`, use `myhost.soap.cloudax.dynamics.com` as the SOAP hostname.
  - If you don't know the SOAP hostname of your test environment, you can find it in the web.config file for the AOS server in `Infrastructure.SoapServicesUrl`.
  - If your test environment is a user acceptance testing (UAT) or higher-tier sandbox environment that has no Remote Desktop access, the SOAP hostname is equal to the hostname.

- **Admin User Name** – The email address of an admin user in the test environment. The admin user name must be the email address of a user who belongs to the System Administrator role on the Finance and Operations test environment that RSAT is connecting to. The user account (email address) must also belong to the same tenant as the test environment. For example, if your test environment's default tenant is contoso.com, the admin user must end with @contoso.com.

- **Thumbprint** – The thumbprint of the authentication certificate that you're using. If you don't have Remote Desktop Protocol (RDP) access to your environment, follow the steps lower in this article to download the certificate from Lifecycle Services and paste the thumbprint here. Otherwise, if you do have RDP access to the environment, follow these steps to generate a self-signed certificate.
  1. Select **New** to create and install a new authentication certificate. When prompted, place the .cer file somewhere so you have it saved for your records.
  2. When the process completes, the new certification is installed in the local machine's trusted root store.

```plaintext
Message

The certificate has been successfully created and added to the Trusted Root
Store.

OK
```

3. The thumbprint of the newly created certificate is automatically inserted on this form. Copy this thumbprint, you will use it in the next section to configure the AOS to trust the connection.

- **Company name** – Specify a company name to use as your default company during creation of Excel parameters files. It can be changed later by editing an Excel file.

Run setting
Configure your local settings.

- **Working directory** - Folder location for storing test automation files, including Excel test data files. For example: `C:\Temp\RegressionTool`.
- **Default browser** - Select the browser to use for test execution. RSAT supports (the new) Microsoft Edge, Microsoft Internet Explorer, and Google Chrome. We recommend Microsoft Edge, which you can download from [Introducing the new Microsoft Edge](https://www.microsoft.com/en-us/surface/windows-10-edge).

Select **Ok** to apply your settings and close the dialog box. Select **Cancel** to cancel your changes and close the dialog. The **Save As** and **Open** buttons allow you to save your settings for reuse later. Select **Save As** to save your current settings into a configuration file on your computer. Select **Open** to restore your settings from a configuration file.

Optional settings
Select the **Optional** tab to configure optional settings.

- **Test Run Prefix** – RSAT reports test run results to Azure DevOps. Test runs are named using the following convention: `<Run ID> <Prefix> <Test Suite>`. Use this setting to set the `<Prefix>`.

- **Test Run Timeout** – The time-out (in minutes) of a test run. All active windows are closed and pending test cases fail when this time-out is reached.

- **Test Action Timeout** – The time-out (in minutes) of individual test steps. When a test step times out, the test case fails.

- **Pause between steps** – The number of seconds to pause between test steps during automated execution of a test case. The default value is 0 (zero). Set this value to force a pause during test execution, for auditing or investigative purposes. You can also specify a pause for an individual test case by changing the **Pause between steps (Seconds)** parameter on the **General** tab of the Excel parameter file for the test case.

- **Fail test on first validation error** – By default, if a test case has multiple validation steps, and there is a validation failure, the test case stops running when the first failure occurs. The test case is then marked as failed. If you want test cases to continue to run until all validations are completed, clear this option. The test case can then evaluate all validations.

- **Fail test on Infolog error** - Check this option to force test cases to fail when an error is encountered in the Finance and Operations Infolog during test case execution.

- **Abort test suite execution on failure** – By default, a test suite run continues even if one of the test cases fails. If you check this setting, the test run is aborted if a test case fails. All the remaining test cases will have a status of **Not Executed**.

- **Enable local file validation rules** - Check this setting to validate whether your test cases are ready for execution. See Validate readiness of test automation files for more details.

- **Enable upload to Azure DevOps** - To prevent accidental upload to Azure DevOps (therefore overriding project-wide recordings and automation files), you can uncheck this setting. This is especially useful when RSAT is deployed on a client machine for execution purposes only, and you want to prevent users from making permanent changes to the test cases.

- **Cloud provider** – Select the provider of the cloud tenant of your test environment. Supported providers are **Global** (Public cloud) and **China** (Sovereign cloud).

  **IMPORTANT**
  
The **Cloud provider** setting is required, and the selected value must be **China** if your Finance and Operations apps were deployed in 21Vianet.

**Configure the test environment to trust the connection**

*If your AOS allows for Remote Desktop connections*

After creating the certificate, configure AOS to trust the test automation connection. On a multi-AOS environment, repeat the following steps for all AOS machines.

1. Open a Remote Desktop connection to the AOS machine.

2. Open IIS and find AOSService in the list of sites.
3. Right-click AOSService, then select Explore.

4. Open and find the file wif.config.

5. Update the wif.config file by adding a new authority entry, as shown in the following example. Use 127.0.0.1 for the authority name and paste your certificate thumbprint.

If you have no Remote Desktop access to the server

In cases where your Remote Desktop Protocol (RDP) access is removed, such as Microsoft-managed or self-service type sandboxes, Microsoft will generate the certificate for your environment and have it pre-configured. Follow these steps to retrieve the RSAT certificate and use it using the LCS user interface. For automation, there is information on the Fetch an environment's RSAT certificate in a zip file API reference page.

1. Under Maintain on your environment details page in Lifecycle Services you'll see two new options.
   - Download RSAT certificate
   - Regenerate RSAT certificate
Use the **Download** button to retrieve the certificate bundle as a .zip file.

2. You'll receive a warning that a clear-text password will be displayed on your screen. You will need the password in subsequent steps. Select **Yes** to continue.

3. Copy the clear-text password for later use. You'll see the .zip file has been downloaded. Inside the .zip file is a certificate (.cer) and a personal information exchange (.pfx) file. Unzip the file.

4. Install the certificate in the local machine's trusted root store:
   - Double-click the certificate (.cer) to open it, and then select **Install Certificate**.
   - Select *local machine*, and then browse to the *Trusted Root Certification Authorities* store to install it in the trusted root store.

5. Install the pfx file in the local machine's personal store:
   - Double-click the personal information exchange (.pfx) file to open it, and select **Local Machine**.
   - Enter the password saved in step 2, and browse to the *Personal* store.

6. Double-click the certificate file to open it. Browse to the **Details** tab, and scroll down until you see the **Thumbprint** section. Select **Thumbprint**, and note the ID in the text box. Select or paste this thumbprint in RSAT settings.
You can now run your tests against the environment using this certificate. The certificate will be autorotated by Microsoft before it expires, at which time you will need to download a new version of this certificate starting from step 1 above. For self-service environments, this will be rotated every 60 days during a downtime window that is closest to the expiry. These downtime windows include customer initiated package deployment, and database movement operations that target the environment.

Manual configuration of authentication certificates

Optionally, you can manually configure the RSAT authentication certificate.

If you are not familiar with this process, get help from your system administrator. Make sure you have Windows Kits installed on your machine. If you do not have Windows Kits installed on your machine, you can download the Windows 10 SDK from Windows 10 SDK. You will need these components for the steps described in this document.

- Windows SDK Signing Tools for Desktop Apps
- Windows SDK for UWP-Managed Apps.

Generate the certificate

You must generate the certificate file on the RSAT client computer. The certificate must be generated on the same computer that the test tool is running on. To generate the certificate file, follow these steps:

1. Create the C:\Temp folder if it does not already exist on your computer.

2. Open a command-line window as Administrator.

3. Go to the folder where you installed the Windows SDK. Your exact folder may be different, depending on where you have installed the windows SDK. You can also use Windows Kits 8.1.

   ```
   cd c:\Program Files (x86)\Windows Kits\10\bin\10.0.17763.0\x64
   ```

4. Run the following command. When you are prompted to enter a private key password, enter None.

   ```
   makecert.exe -n "CN=127.0.0.1" -ss My -sr LocalMachine -a sha256 -len 2048 -cy end -r -eku 1.3.6.1.5.5.7.3.1 c:\temp\authCert.cer
   ```
Install the certificate to the Trusted Root

To install the certificate, follow these steps:

1. Double-click authCert.cer to install the certificate.

2. Select Install Certificate.

3. Select Local Machine > Place all certificates in the following Store > Browse > Trusted Root Certification Authorities and select Next through each screen.

4. Leave the Password field blank.

5. In the Certificate dialog box, browse to Details and look for Thumbprint.

6. Copy and save the thumbprint. You will need it to configure the AOS as described earlier in this topic.
This topic explains how to load test cases from Azure DevOps, generate automation files, modify test parameters, run and investigate results, and save your work back to Azure DevOps.

Load test cases and create automation files

In RSAT, select the **Test Plans** tab and then select **Load** to download test cases and test case automation files. All test cases (and their corresponding attachments) belonging to the test plan specified in the **Settings** tab are downloaded to the local working directory.

Test cases are organized by test suites under a common test plan. These are test suites you created in your Azure DevOps project. Using this tool, you can work with one test suite at a time.

If the tool fails to load any test case, verify that your test plan in Azure DevOps is properly created and contains the desired test suites and test cases.

If this is the first time you are using this test plan, the **Parameters File** column will be blank. You must create test automation files for your test cases.

A test case requires the following attachments for successful execution:

- **A recording file**: This is the recording file created by the Finance and Operations Task recorder. It defines the steps of your test case. It is typically named `recording.xml` but you can also name it to match the test case title in Azure DevOps. It is attached to the test case in Azure DevOps and downloaded into the attachment folder of the local working directory of the test case.

- **Test automation files** consisting of a **test parameter file** (Microsoft Excel file) containing configurable test case parameters and **test execution files**: These files are generated by RSAT to enable automated execution of the test recording. Filenames are suffixed by `_Base.cs`, `_Base.xml`, and `_Base.dll`.

When you select **New**, test automation files are generated in your working directory. The Excel test parameter files will appear on the grid under **Parameters File**.
You can also generate test execution files only, without overwriting your parameter files. Select New > Generate Execution Files to regenerate only execution files and leave Excel files unaffected.

You must generate test execution files when you install a new version of the tool, and when you modify or load a new version of the recording file. In this way, you update your execution files but also preserve the test parameter files.

Modify test parameters

This section describes how to modify Excel files to specify input and validation parameters for your test run. Select one or more test cases to modify, and then select the Parameters button (Microsoft Excel symbol) on the toolbar. An Excel window opens for each test case that you selected. Alternatively, you can open the Excel files directly from the working directory.

In addition to the General tab, the Excel parameter file contains a MessageValidation tab and a TestCaseSteps tab.

Select the TestCaseSteps tab to configure input and validation parameters of your test case. Input and validation parameters are placed directly next to their corresponding test case step, enabling test authors with context and a simple experience. When you modify parameters, it is clear what steps of the test case you are affecting. You can enter values or formulas in context. Color coding differentiates input parameters from validation steps.
Reusable variables that are copied while recording the test case are also shown in context of the test case step. You can easily locate a variable and copy it to use in subsequent steps and formulas. For more information, see Copy variables to chain test cases.

Save the Excel files when you are done making edits.

**Run a test as a specific user**

By default, tests are executed using the admin role. If you want to run the test as a specific security role, specify the email address of a user under the Test User parameter in the General tab of the Excel parameter file. The Test User must be a valid user of the environments you are connecting to. The test will run under the security roles that the specific user belongs to. You need version 1.200 or newer for this feature to be functional.
Run a test in the context of a specific company

The **General** tab of the Excel parameter file also allows you to specify the name of a legal entity (Company). The test will run in the context of this company. You can specify your default company in the **Settings** dialog box of the tool.

Pause after a specific test step

You can insert a pause between specific test steps. Navigate to the **TestCaseSteps** tab of the Excel parameters file and insert a value (in seconds) in the pause column of a test step. This will pause test cases execution after the test step is completed.

If you don’t see the Pause column, you are using an older version of the Excel parameters file and need to regenerate it. Select the desired test case, then go to **New > Generate Test Execution and Parameter Files**. This may override edits you have made to the parameters file, so you should back up the existing Excel file first.

Other notable test case execution settings

You may find the following settings useful. They are available on the **General** tab of the Excel parameter file.

- **Fail on warning message in the Infolog**: By default, test cases fail when an error occurs or a validation step fails. If you also want a test case to fail in response to a warning message, set the **Fail on warning message in the Infolog** option to **True**. This is useful, for example, if a test case adds a duplicate customer record. The default setting is **False**.
- **Abort test suite execution on failure**: If you set the **Abort test suite execution on failure** option to **True**, execution of the test suite is aborted if the test case fails. All the remaining test cases will have a status of **Not Executed**. The default setting is **False**.
- **Pause between steps**: The number of seconds to pause between test steps. This will affect every test step. The default value is 0 (zero).

Infolog and message validation

Excel parameter files that are generated using version 1.200 or newer contain a **MessageValidation** tab.
You can enter messages in this tab under **Message Validation**. After a test case completes execution, it validates that the messages specified here appear in the Infolog. The test case will fail if these messages are not found.

You can specify any expected messages including error messages. Any message specified in this section will cause a test case to fail unless it is found in the Infolog during execution. Two operators are available: **Equals** and **Contains**. If you use **Equals**, then RSAT performs a string comparison with all messages in the Infolog and fails validation if the full message is not found. If you use **Contains**, then RSAT will validate that at least one message in the Infolog contains the string you specify.

![Message Validation Table](image)

You can configure whether string comparison is case sensitive or not in the **Optional** page of the **Settings** tab.

**Run**

Select **Run** to execute the selected test cases. Only test cases with existing automation files can be run. The tool will open and execute these tests with the data you entered in Excel.

You can modify the order in which test cases are executed using the up and down arrow buttons.

**Pause prior to a test case run**

You can add a pause before a test case starts execution. If you want to pause, update the cell **Pause (seconds)** on the **General** tab of the Excel parameters file of the desired test case.

**Stop a run**

When a test run is in progress, you can select the **Stop** button on the toolbar to cancel the run. Execution stops after the currently running test case completes. The remaining test cases will be marked as **Not Executed** in Azure DevOps.

**Validate readiness of test automation files**

Optionally, you can turn on a setting that validates whether your test cases are ready for execution. This setting prevents unknown errors related to the validity of recordings and test automation files. This option is available as of RSAT version 1.210. You can enable this by selecting the **Settings** tab and then selecting the **Optional** tab.
When enabled, a background process continuously validates the following for each test case.

- The local working directory exists.
- The Excel parameter file exists.
- Test automation files (binary and Xml files) needed for execution exist.
- Test automation files are compatible with current version of RSAT. You must regenerate test automation files when you install a new version of RSAT.
- Test case ID specified in the Excel parameter file matches the test cases ID in Azure DevOps.

The Valid column in the grid indicates the result of the validation process. If validation fails, click on the X in the Valid column to view the error and recommended action.
Investigate results

When all test cases complete execution, **Pass** or **Fail** will be populated in the **Result** column. You can click on the result to see error messages.

Additional investigation details are available in Azure DevOps. To view this information, from your Azure DevOps project page, go to **Test > Runs**.

Select the desired test run. It will include the results of all tests that were executed during that run.
You can open a failed test result and review the **ErrorMessage** section for information about the failure.

### Summary

- **Failed**

- **Run by** not available
- **Test Plan** 28
- **Priority** 0
- **Test suite** Acceptance Test Suite 1
- **Test Case** Business Process Test Demo | Create Purchase Order
- **Configuration** Windows 10

### Error message

**Steps:**
- Navigate to: Purcheditlines (purchformletter_packingslip)
- Click Select.
- In the list, mark the selected row.
- In the Criteria field, type a value.
- Click OK.
- In the list, mark the selected row.
- In the Product receipt field, type a value.

**Warning:** Product receipt PRL was already used as on date 12/7/2018.
- Click OK.
- **Error:** Posting

**Error:** An error occurred during update

**Information:** Operation canceled: Product receipt posting

**ERROR:**
- **Infolog contains:**
- **Error:** Posting
- **Error:** An error occurred during update

All error messages are also available locally under

`C:\Users\$YourUserName\AppData\Roaming\regressionTool\errmsg-<TestCaseId>.txt`

### Test response times

In addition to execution logs, the duration of a test case is also available in the test result.

<table>
<thead>
<tr>
<th>Outcome</th>
<th>Test Case Title</th>
<th>Priority</th>
<th>Duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Passed</td>
<td>(Business Process Test Demo) Create Purchase Order</td>
<td>0</td>
<td>00:1:27.247</td>
</tr>
</tbody>
</table>

You can also review the response time of each step of the test case by opening the **BaseTime.xml** file attached to the test result.

### Attachments (2)

<table>
<thead>
<tr>
<th>Name</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create_Purchase_Order_40_BaseTime.xml</td>
<td>... 4K</td>
</tr>
<tr>
<td>Create_Purchase_Order_40_BaseLog.txt</td>
<td>... 1K</td>
</tr>
</tbody>
</table>

You need version 1.200 or newer for response times to be available.

### Upload to Azure DevOps to commit your work

To commit your work to Azure DevOps, select **Upload**. This uploads recordings and test automation files, including Excel test parameter files, of all selected test cases to Azure DevOps for future use. After test
automation files are uploaded to Azure DevOps, the next time you use the Regression suite automation tool, even from a different computer, you can simply use **Load** and then **Run**, without generating test execution files or editing Excel parameter files.

In the upload menu, you also have the option to upload recording files (Task recordings) only.

If you are unsure what test cases to select, and you want to commit all changes (since last load) to Azure DevOps, select **Upload all modified automation files** in the upload menu.

### Process compliance

RSAT provides capabilities for managing the readiness of test cases. It also provides a sign-off process for test runs. This is configurable in the **Process** tab under Settings.

**Enforce test case readiness**

You can set up the test case so that it isn’t run unless it has a status of **Ready** in Azure DevOps. Select the **Enforce test case readiness** check box. By default, the check box is cleared.

**Signoffs**

When your test run is complete, RSAT can create sign-off work items in Azure DevOps. Select the **Sign-off tasks** check box. Then set the type of work item that should be created for each person who signs off. You can select the **Functional**, **IT Manager**, or **Team Manager** role for sign-offs, and then specify appropriate email addresses. Work items will then be created in Azure DevOps and assigned to owners for approval.
Regression suite automation tool (RSAT) version 2.2 and later lets you maintain test cases and attachments in the tool itself. In earlier versions, you had to use Microsoft Azure DevOps to maintain test cases and then switch to RSAT to run tests. Therefore, newer versions offer better usability and help improve productivity. Many operations can be done completely in RSAT, and it’s also easier to work with test suites.

Test plans and test suites continue to be maintained in Azure DevOps.

To use this feature, you must enable the Enable upload to Azure DevOps option. Changes that are made in RSAT are then automatically uploaded to Azure DevOps and will be available there. Therefore, test suites will include the updated test cases that are available to other users or that can be run in Azure DevOps by a pipeline.

**View test case information**

Follow these steps to view information about a test case.

1. In the **Test Cases** grid, find the relevant test case, and hover over the row until an ellipsis button (…) appears between the **Title** and **Parameters File** columns.

2. Select the ellipsis button. The menu that appears has two commands: **Open test case** and **Delete Test Case**.
Create a test case that has attachments

3. Select **Open test case** to open the **Test Case information** dialog box.

The **Test Case information** dialog box shows the following information about the test case:

- The name that is assigned to the test case in the test suite appears at the top of the dialog box and can be changed.
- The recording name appears under the test case name. This name is taken from the recording XML file that was used when the recording was made in Task Recorder in the Finance and Operations app or by using the point of sale (POS) client.
- The **Attachments** grid shows the list of attachment files that are available with the test case. You can also find this list by using the **Directory** action under the attachments subfolder.

**Create a test case that has attachments**

Follow these steps to add a new test case by using RSAT.

1. Select the test suite that you want to add a new test case to (**Procure to Pay – v2** in this example). Then select **New Test Case** to open the **Test Case information** dialog box.
2. Enter the name of the test case, and add attachment files. These files include the recording XML file that contains steps for the test case. To add attachment files, select Add, and then, in the dialog box that appears, select the files to add as attachments.

3. When you’ve finished, select Save to save the new test case or Cancel to discard it.

When you save a new test case, RSAT copies the attachment files that you selected into your local RSAT working directory. It maintains the copies there so that they can be used with the test case.

There is no feature that automatically clones test cases from one test suite to another. However, you can manually clone test cases by following these steps.

1. Create a test case as described in the previous procedure. As part of this step, add the recording XML file.
2. Save the new test case, and make a note of the CaseID value that is assigned to it.
3. You can add a parameter Excel file to the new test case. However, the file name must match the new CaseID value. Copy the parameter Excel file from the test case that you’re cloning, and change the file name of the copy so that it matches the new CaseID value.
4. Open the new parameter Excel file, and change all instances of the old CaseID value to the new CaseID value.
5. After you’ve finished updating the new parameter Excel file, add it to the new test case as an attachment.

Alternatively, you can generate a parameter Excel file for the new test case first, and then manually edit it so that it matches the parameter Excel file of the test case that you’re cloning.

**Remove an attachment from a test case**

You can remove attachments from a test case when you no longer require them.
In the **Test Case information** dialog box, select and hold (or right-click) the row for the attachment file, and then select **Remove**.

You can also use this procedure if you’ve edited the recording XML file and you want to upload the new version to the test case. In this case, you should first remove the existing file and then add the new file.

### Delete a test case

Follow these steps to delete a test case.

1. In the **Test Cases** grid, find the relevant test case, and hover over the row until an ellipsis button (...) appears between the **Title** and **Parameters File** columns.

2. Select the ellipsis button, and then select **Delete Test Case** on the menu.

3. Confirm that you want to delete the test case, and optionally specify a reason for the deletion.

A test case that you delete in RSAT is removed from the current test suite, both locally and in Azure DevOps.

In Azure DevOps, work items represent test cases, and test suites contain links to the test case work items. A test case is reused by linking to it from more than one test suite. When a test case is deleted in RSAT, RSAT determines whether the test case is linked to one test suite or more than one test suite. If the test case is used only by the current test suite, RSAT deletes the Azure DevOps work item that represents the test case. If the test case is used by other test suites, RSAT doesn’t delete the work item itself. Instead, it deletes only the link to the work item.
An important component of a test case is validation of expected values. You can define validation parameters during the authoring of your test cases using Task Recorder. While recording, right-click on a control and select **CurrentValue** under the **Task Recorder > Validate** menu. This action becomes a validation step that you can use with the Regression suite automation tool. The control value will become a validation variable in the automatically generated Excel parameters file. The menu item is shown in the following image.

For more information about how to create task recordings, see [Task recorder resources](#).

When RSAT generates the Excel parameter file for a test case, validation steps are added as shown in the image below. You can enter the expected value to use during execution of the test case.

![Excel parameter file with validation steps](#)

**Validate expected values using operators**

You can also use operators in validation steps to validate that a variable is not equal, less than, or greater than a specified value. To use this feature, open the **Settings** tab and select the **Optional** tab. Turn on the setting named **Use operators for validation**. This option is available as of RSAT version 1.210. If you have been using
an older version of the tool, you must regenerate new Excel parameter files to take advantage of this functionality. In the Excel file, a new **Operator** field will appear, as shown in the following image.

When recording test cases, Task Recorder supports additional validation action:

- Validate whether a control is enabled or disabled.
- Validate whether a control is editable or read-only.

To take advantage of this validation, you need to be use a Finance and Operations app running on 10.0.13 (or newer) and RSAT 2.0 (or newer). For more information, see Validate.
One of the key features of the Regression Suite Automation Tool is the chaining of test cases, that is, the ability of a test to pass values to other tests. Test cases are executed according to their defined order in the Azure DevOps test plan, which can also be updated in the test tool itself. It is important to correctly order the tests if you want to pass variables from one test case to the other.

To save the value of a variable while recording the test in Task Recorder, right-click the field and select Task recorder > Copy, as shown in the following image. Copying will save the variable in the recording file. This variable can be used in subsequent tests.

When RSAT generates the Excel parameters file, saved variables appear in the Saved variables table on the General Tab. These variables also appear in the context of the test case steps in the TestCaseSteps tab. In the image below, the purchase order ID value was copied during the recording of the test case (step 5). This value is stored in a variable named ({{PurchCreateOrder_PurchTable_PurchId_86_Copy}}).
Support for formulas of saved variables

To reuse these variables during test playback, copy the variable name and use it in place of a parameter value in the data file of another test (or the same test), as shown below.

Variables can be used in the same test case where they are defined and can also be passed between tests during the same test run.

Support for formulas of saved variables

You can create formulas that contain saved (copied) variables. If you have been using an older version of the Regression Suite Automation Tool, you will need to regenerate new Excel parameter files to take advantage of this functionality. Supported operators are +, -, /, and ''. Only numerical variables can be used in the Regression Suite Automation Tool formulas. Strings or dates are not supported. Always specify variable names within double braces {{varname}}. For example, {{var1}} + {{var2}}.

In the image below, two different variables are used in a formula.
As of RSAT version 1.220, you can also use Excel functions, such as ROUND, CONCAT, and UPPER, to create formulas with RSAT variables. This feature is implemented using the Excel formula evaluation functionality, so any function supported by Excel is supported by RSAT.

For example,

- To round a value into the nearest whole number, use:
  
  ```excel
  =ROUND({{Item_Price_3274_Copy}}, 0)
  ```

- To concatenate strings, use:
  
  ```excel
  =CONCATENATE({{AccountNum_3274_Copy}}, " ", {{ AddressBP_Locator_3274_Copy}})
  ```

- To calculate and format a date and convert it to a string, use:
  
  ```excel
  =TEXT(DATEVALUE({{SystemDate_CurrentDate_3276_Copy}}) - 1, "mm/dd/yyyy")
  ```

Always convert RSAT date values to text for reliable test case execution.

RSAT evaluates these formulas during test execution, so you must precede the formula with a single quote `’` to prevent Excel from attempting to prematurely calculate the formula. An example is shown in this image.

Use variables in message validation

You can also use a saved variable as part of a string in the Message Validation tab. Here is an example that validates that the message Customer account {{variable name}} already exists. It appears in the Infolog during test execution. {{variable name}} is a variable that is copied during the recording.

Saved (Copied) variables can be used within the same test case or across more than one test case in the same test suite.
<table>
<thead>

The Regression suite automation tool (RSAT) lets you use the same task recording with multiple test cases, so that you can run a task with different data configurations. Select a test case in the Regression suite automation tool and then select New > Create Derived Test Case. This creates a child test case in Azure DevOps. The resulting derived test case is linked to its parent test case in Azure DevOps. It has an Excel parameters file attached but no recording file. The derived test case will appear in the Regression suite automation tool grid under the same test suite with the Derived column selected. By default, derived test cases are named after their parent test case with a numeric suffix.

In the following image, a derived test case has been created from a test case named Create a Sales Order and Validate - v2. The derived test case has been renamed (in Azure DevOps) to Create a Sales Order and Validate - v2 (Fail validation).

In Azure DevOps, a derived test case is a child item of the Create a Sales Order and Validate - v2 test case and is tagged with the special keyword RSAT:DerivedTestSteps.

When you run a derived test case, it will use the recording of its parent test case and its own copy of the Excel parameters file. This will allow you to run the same test with different parameters without the need to maintain more than one recording.
A derived test case does not need to be part of the same test suite as its parent test case, and you can use it in another suite. You can also rename a derived test case. You can edit the Excel parameters file of a derived test case to run it with a different user, a different company, or with different input and validation parameters than its parent test case.
The format of parameter Microsoft Excel files that are used with Regression suite automation tool (RSAT) changed in the 2.0 release. The format is now more intuitive and shows test steps. New test cases that are created in RSAT version 2.0 and later automatically generate parameter files in the new format. However, you might have tests that were created before version 2.0 and that still use the old format. RSAT will continue to support running test cases that use parameter files in the old format at least until the next major release. RSAT can also upgrade old parameter files to the new format.

Parameter files can be freely edited in Excel. In some situations, a parameter file can't be fully upgraded, and some manual work is required to complete the process. The next section explains the mechanics of the upgrade process.

**Upgrade process**

The upgrade process tries to do a full upgrade. However, in some situations, this process can't be safely completed.

When the full upgrade process can be completed, the old parameter file is replaced with a new one. A copy of the original file is created, and _BAK is appended to the file name.

If only part of the parameter file can be safely upgraded, the original file isn't changed. Instead, a new file is created, and _PARTIAL is appended to the file name. The partial file contains the information that could be upgraded. You can use the partial file to manually transfer missing parts from the original file and complete the new file. When you've finished, rename the original file to a backup name (for example, append _BAK to the file name). Then rename the new file by removing _PARTIAL from the file name. The new file then becomes the new parameter file.

You can continue to use the old parameter file until the new file is ready. RSAT will continue to support the old format for parameter files at least until the next major release.

The upgrade process can usually upgrade unedited parameter files. It can also upgrade files where only cell values have been changed in the file. However, if additional cells have been added and referenced, the upgrade process can't be completed automatically. In this case, the partial file will include cells that have the value #MISSING. This value indicates that cell references are missing. You must manually add the information from the original parameter file to the new partial file.

From now on, add new cells to the new **CustomParameters** sheet in the parameter file, just as they are added in the partial file.

In RSAT release 2.2 and later, the parameter file has a sheet that is named **CustomParameters**. This sheet is included to help future-proof the upgrade of parameter files. If you add cells, add them to this sheet.

If you added a cell to the old parameter file and assigned a name to that cell, the named cell is automatically moved to the **CustomParameters** sheet during the upgrade, provided that its value doesn't reference other
After you’ve finished moving your added cells to the partial file, if any references on the **TestCaseSteps** sheet have #MISSING as the value, change the references so that they match the relevant cells on the **CustomParameters** sheet. Ideally, you should always reference cells by their assigned name (for example, **MyQuantity**), not by the cell identifier (for example, **E4**).

NOTE

As a best practice, you should assign names to any cells that are added to the **CustomerParameters** sheet. Then reference the cells by name from test case steps.

After the upgrade, you should run your test cases to make sure that the new parameter file produces the expected results. Complete this step both when the upgrade was fully completed and when the upgrade required manual work.

When you’ve finished creating and testing the new files, you can delete the backup and partial files.

**Run the parameter file upgrade process**

To upgrade the parameter files, follow these steps.

1. Open RSAT.
2. Select that test cases that have the parameter files that you want to upgrade.
3. On the **New** menu, select **Upgrade Parameter files (will auto generate Test Execution files)**.

The parameter files for all the selected cases are upgraded.

The upgrade process skips test cases where the parameter file is already in the new format. A parameter file is considered upgraded if it contains the **CustomParameters** sheet.

When the upgrade process is completed, a message box appears that shows a summary. The summary includes the following information:

- The total number of selected test cases that were marked for upgrade.
- The number of successful upgrades. For these upgrades, there are new parameter files and _BAK files.
- The number of failed upgrades. For these upgrades, there are new _PARTIAL files.
- The number of skipped upgrades.
An explanation of the results.

The following illustration shows an example of the summary message box.

For a failed upgrade, you can find more information by selecting the yellow triangular warning symbol next to the test case title. The following illustration shows an example of the message box that appears.

IMPORTANT

You can run the upgrade repeatedly. In this case, newly upgraded parameter files will be skipped. However, new partial files will overwrite existing partial files. We recommend that you complete all partial files and rename them before you rerun the upgrade.
This tutorial walks through some of the advanced features of the Regression suite automation tool (RSAT), includes a demo assignment, and describes strategy and key learning points.

**Notable Features of RSAT and Task recorder**

**Validate a field value**

RSAT allows you to include validation steps within your test case to validate expected values. For information about this feature, see the article [Validate expected values](#).

The following example shows how you can use this feature to validate whether the on-hand inventory is more than 0 (zero).

1. In the demo data in the **USMF** company, create a task recording that has the following steps:
   a. Go to **Product information management > Products > Released products**.
   b. Use the Quick Filter to find records. For example, filter on a value of **1000** for the **Item number** field.
   c. Select **On-hand inventory**.
   d. Use the Quick Filter to find records. For example, filter on a value of **1** for the **Site** field.
   e. In the list, mark the selected row.
   f. Validate that the value of the **Total available** field is **411.0000000000000000**.

2. Save the task recording as a **developer recording** and attach it to your test case in Azure Devops.

3. Add the test case to the test plan, and load the test case into RSAT.

4. Open the Excel parameter file and go to the **TestCaseSteps** tab.

5. To validate whether the inventory on-hand will always be more than 0, go to the **Validate Total Available** step and change its value from **411** to **0**. Change the value of the **Operator** field from an **equal sign (=)** to a greater than sign (**>**).

7. Select **Upload** to save the changes that you made to the Excel parameter file to Azure DevOps.

Now, if the value of the **Total Available** field for the specified item in inventory is more than 0 (zero), tests will pass, regardless of the actual on-hand inventory value.

**Saved variables and chaining of test cases**

One of the key features of RSAT is the chaining of test cases, that is, the ability of a test to pass variables to other tests. For more information, see the article [Copy variables to chain test cases](#).

**Derived test case**

RSAT lets you use the same task recording with multiple test cases, enabling a task to run with different data configurations. See the article [Derived test cases](#) for more information.
**Validate notifications and messages**

This feature can be used to validate whether an action occurred. For example, when a production order is created, estimated, and then started, the app shows a "Production – Start" message to notify you that the production order has been started.

You can validate this message through RSAT by entering the message text on the `MessageValidation` tab of the Excel parameter file for the appropriate recording.

After the test case is run, the message in the Excel parameter file is compared to the message that is shown. If the messages don't match, the test case will fail.

**NOTE**

You can enter more than one message on the `MessageValidation` tab in the Excel parameter file. The messages also can be error or warning messages instead of informational messages.

**Snapshot**

This feature takes screenshots of the steps that were performed during task recording. It is useful for auditing or debugging purposes.

- To use this feature while running RSAT with the user interface, open the `Microsoft.Dynamics.RegressionSuite.WindowsApp.exe.config` file under the RSAT installation folder (for example, `C:\Program Files (x86)\Regression Suite Automation Tool`), and change the value of the following element from `false` to `true`.

  ```xml
  <add key="VerboseSnapshotsEnabled" value="false" />
  ```

- To use this feature while running RSAT by the CLI (for example, Azure DevOps), open the `Microsoft.Dynamics.RegressionSuite.ConsoleApp.exe.config` file under the RSAT installation folder (for example, `C:\Program Files (x86)\Regression Suite Automation Tool`), and change the value of the following element from `false` to `true`.

  ```xml
  <add key="VerboseSnapshotsEnabled" value="false" />
  ```

When you run test cases, RSAT generates snapshots (images) of the steps and saves them in the playback folder of the test cases in the working directory. In the playback folder, a separate subfolder is created named `StepSnapshots`. That folder contains snapshots for the test cases that are run.
Assignment

Scenario
1. The product designer creates a new released product.
2. The production manager initiates a production order to bring the stock level to two pieces.
3. Manufacturing starts and ends the production order, and verifies that the on-hand quantity is two pieces.
4. The sales team receives an order for four pieces of the new product. Therefore, the sales team updates the net requirements via the dynamic plan. Because no additional capacity is available, the default order policy is set to “buy instead of make.” Therefore, a planned purchase order is created.
5. The buyer adds a vendor, firms the planned purchase order, and then confirms the purchase order.
6. When the goods that were purchased arrive at the store, the store operator searches the related purchase order and receives the goods. Because the order is now completed, goods can be picked and packed against the sales order.
7. Finance posts the purchase invoice and sales invoice.

The following illustration shows the flow for this scenario.

The following illustration shows the business processes hierarchy for this scenario in the LCS Business Process Modeler.
**Strategy – Key learning**

**Data**

- Make sure that you have representative data volumes (a copy of production/golden configuration data plus migrated data).

- When you generate new data via Task recorder, create test names that won’t conflict with existing names (for example, use a prefix such as RSATxxx).

- Use Azure Point-In-Time restore to rerun tests in non-Tier 1 environments.

- Although you can use the **RANDOM** and **NOW** Excel functions to generate a unique combination, the effort is considerably high. Here is an example.

    ```
    product =  "AT" &TEXT(NOW(),"yyymmdhhmm")
    ```

**Task recorder**

- Define scenarios before you start recording. A well-managed project has predefined test scenarios. To build a test case, consider how predictable the outcome of those test scenarios is.

- Split recordings if they are performed by different roles, or if there is waiting time or an external event before the next step.

- Avoid selecting values in lists. Instead, use text formats, such as **FIFO**, **AudioRM**, and **SiteWH**. When you select in a list, the position of the value in the list is recorded, not the value itself. If items are added to that list, the position of the value can change. Therefore, your recording will use a different parameter, and the rest of the scenario might be affected.

- Think about multi-user behavior. For example, don’t assume that your newly created sales order will always be automatically selected. Instead, always use the filter to find the correct order.

- Use the Copy function in Task recorder to save the name of a newly created product so it can be used in...
chained test cases.

- Use the Validate function in Task recorder to set checkpoints that verify that steps have been run correctly.

**RSAT**

- To run the test in another company, you can change the company on the *General* tab of the Excel parameter file. Make sure that settings and data are available in the newly selected company.
- You can change the test user on the *General* tab of the Excel parameter file. Specify the email ID of the user who will run the test case. In this way, the test case can be run by using the security permissions of the specified user.
- To wait before the test is started, you can define a pause on the *General* tab of the Excel parameter file. This pause can be used in a batch job (for example, if a workflow must be run before the next step can be performed.)

**Advanced scripting**

**CLI**

RSAT can be called from a *Command Prompt* or *PowerShell* window.

```
NOTE
Verify that the TestRoot environment variable is set to the RSAT installation path. (In Microsoft Windows, open Control Panel, select System and Security > System > Advanced system settings, and then select Environment Variables.)
```

1. Open a *Command Prompt* or *PowerShell* window as an admin.

2. Navigate to the RSAT installation directory.

   ```
   cd "c:\Program Files (x86)\Regression Suite Automation Tool"
   ```

3. List all commands.
C:\Program Files (x86)\Regression Suite Automation

Usage:
   Microsoft.Dynamics.RegressionSuite.ConsoleApp.exe command
or
   Microsoft.Dynamics.RegressionSuite.ConsoleApp.exe /settings "C:\Path to\file.settings" command

Available commands:
   ?
   about
   cls
   download
   edit
   generate
generatederived
generatetestonly
generatetestsuite
   help
   list
   listtestplans
   listtestsuite
   listtestsuitenames
   playback
   playbackbyid
   playbackmany
   playbacksuite
   quit
   upload
   uploadrecording
   usage

?  Shows help about all available commands and their parameters.

? : Optional parameters

command : Where [command] is one of the commands specified below.

about
   Displays the current version.

Microsoft.Dynamics.RegressionSuite.ConsoleApp  about

cls
   Clears the screen.

Microsoft.Dynamics.RegressionSuite.ConsoleApp  cls

download
   Downloads attachments for the specified test case to the output directory. You can use the list command to get all available test cases. Use any value from the first column as a test_case_id parameter.

Microsoft.Dynamics.RegressionSuite.ConsoleApp  download  [test_case_id] [output_dir]
download: required parameters

   test_case_id : Represents the test case ID.
   output_dir  : Represents the output directory. The directory must exist.

download: examples

download 123 c:\temp\rsat

download 765 c:\rsat\last
edit

Allows you to open parameters file in Excel program and edit it.

Microsoft.Dynamics.RegressionSuite.ConsoleApp edit [excel_file]

eedit: required parameters
  • excel_file: Must contain a full path to an existing Excel file.

eedit: examples
  edit c:\RSAT\TestCase_123_Base.xlsx
  edit e:\temp\TestCase_456_Base.xlsx

generate

Generates test execution and parameter files for the specified test case in the output directory. You can use the `list` command to get all available test cases. Use any value from the first column as a `test_case_id` parameter.

Microsoft.Dynamics.RegressionSuite.ConsoleApp generate [test_case_id] [output_dir]

generate: required parameters
  • test_case_id: Represents the test case ID.
  • output_dir: Represents the output directory. The directory must exist.

generate: examples
  generate 123 c:\temp\rsat
  generate 765 c:\rsat\last

generatederived

Generates a new test case, derived from the provided test case. You can use the `list` command to get all available test cases. Use any value from the first column as a `test_case_id` parameter.

Microsoft.Dynamics.RegressionSuite.ConsoleApp generatederived [parent_test_case_id] [test_plan_id] [test_suite_id]

generatederived: required parameters
  • parent_test_case_id: Represents the parent test case ID.
  • test_plan_id: Represents the test plan ID.
  • test_suite_id: Represents the test suite ID.

generatederived: examples
  generatederived 123 8901 678

generatetestonly

Generates only test execution file for the specified test case in the output directory. You can use the `list` command to get all available test cases. Use any value from the first column as a `test_case_id` parameter.

Microsoft.Dynamics.RegressionSuite.ConsoleApp generatetestonly [test_case_id] [output_dir]

generatetestonly: required parameters
  • test_case_id: Represents the test case ID.
  • output_dir: Represents the output directory. The directory must exist.

generatetestonly: examples
  generatetestonly 123 c:\temp\rsat
  generatetestonly 765 c:\rsat\last

generatetestsuite

Generates all test cases for the specified suite in the output directory. You can use the `listtestsuitenames` command to get all available test suits. Use any value from the column as a `test_suite_name` parameter.
`generatetestsuite`: required parameters

- `test_suite_name`: Represents the test suite name.
- `output_dir`: Represents the output directory. The directory must exist.

`generatetestsuite`: examples

```
generatetestsuite Tests c:\temp\rsat

generatetestsuite Purchase c:\rsat\last
```

`help`

Identical to the `?` command.

`list`

Lists all available test cases.

```
list
```

`listtestplans`

Lists all available test plans.

```
listtestplans
```

`listtestsuite`

Lists test cases for the specified test suite. You can use `listtestsuitenames` command to get all available test suites. Use any value from first column as `suite_name` parameter.

```
listtestsuite [suite_name]
```

`listtestsuitenames`

Lists all available test suites.

```
listtestsuitenames
```

`playback`

Plays back a test case using an Excel file.

```
playback [excel_file]
```

`playbackbyid`

Plays back multiple test cases at once. You can use the `list` command to get all available test cases. Use any value from the first column as a `test_case_id` parameter.

```
playbackbyid [test_case_id1] [test_case_id2] ... [test_case_idN]
```
playbackbyid: examples

playbackbyid 878

playbackbyid 2345 667 135

**playbackmany**

Plays back many test cases at once, using Excel files.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp playbackmany [excel_file1] [excel_file2] ... [excel_fileN]
```

**playbackmany: required parameters**

- **excel_file1**: Full path to the Excel file. File must exist.
- **excel_file2**: Full path to the Excel file. File must exist.
- **excel_fileN**: Full path to the Excel file. File must exist.

**playbackmany: examples**

```
playbackmany c:\RSAT\TestCaseParameters\param1.xlsx
playbackmany e:\temp\test.xlsx f:\rsat\sample1.xlsx c:\RSAT\sample2.xlsx
```

**playbacksuite**

Plays back all test cases from the specified test suite. You can use `listtestsuitenames` command to get all available test suites. Use any value from first column as `suite_name` parameter.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp playbacksuite [suite_name]
```

**playbacksuite: required parameters**

- **suite_name**: Name of the desired suite.

**playbacksuite: examples**

```
playbacksuite suiteName
playbacksuite sample_suite
```

**quit**

Closes the application.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp quit
```

**upload**

Uploads all files belonging to the specified test suite or test cases.

```
Microsoft.Dynamics.RegressionSuite.ConsoleApp upload [suite_name] [testcase_id]
```

**upload: required parameters**

- **suite_name**: All files belonging to the specified test suite will be uploaded.
- **testcase_id**: All files belonging to the specified test case(s) will be uploaded.

**upload: examples**

```
upload sample_suite
upload 123
upload 123 456
```

**uploadrecording**

Uploads only recording file belonging to the specified test cases.

```
```
uploadrecording: required parameters

- **testcase_id**: Recording file belonging to the specified test cases will be uploaded.

uploadrecording: examples

- `uploadrecording 123`
- `uploadrecording 123 456`

usage

Shows two ways to invoke this application: one using a default setting file, another one providing a setting file.

`Microsoft.Dynamics.RegressionSuite.ConsoleApp | usage`

**Windows PowerShell examples**

**Run a test case in a loop**

You have a test script that creates a new customer. Via scripting, this test case can be run in a loop by randomizing the following data before each iteration is run:

- Customer ID
- Customer name
- Customer address

The customer ID will be in the format *ATCUS<number>*\*, where `<number>` is a value between *00000001* and *999999999*.

The following example uses one parameter, `start`, to define the first number that is used. Is uses a second parameter, `nr`, to define the number of customers that must be created. For each iteration, the parameters in the Excel parameter file are changed by using an `UpdateCustomer` function. Then the RSAT command line is called in a `RunTestCase` function.

Open Microsoft Windows PowerShell Integrated Scripting Environment (ISE) in admin mode, and paste the following code into the window that is named `Untitled1.ps1`.
param ( [int]$start = 1, [int]$nr = 1 )
function UpdateCustomer
{
    param ([string]$paramFilename, [string]$sheetName, [string]$CustId)
    $xl = New-Object -COM "Excel.Application"
    $xl.Visible = $false
    $wb = $xl.Workbooks.Open($paramFilename)
    $ws = $wb.Sheets.Item($sheetName)
    $ws.Cells.Item(3, 2).Value = "ATCUS" + $CustId
    $ws.Cells.Item(4, 2).Value = "Automated Test Customer " + $CustId
    $ws.Cells.Item(8, 2).Value = "Automated Test Street " + $CustId
    $wb.Save()
    $wb.Close()
    $xl.Quit()
    [System.Runtime.Interopservices.Marshal]::ReleaseComObject($xl)
}
function RunTestCase
{
    param ( [string]$filename )
    $cmd = "cd c:\Program Files (x86)\Regression Suite Automation Tool\ &&  "
    $cmd = $cmd + "Microsoft.Dynamics.RegressionSuite.ConsoleApp.exe playback "
    $cmd = $cmd + $filename
    cmd /c $cmd
}
$excelFilename = "full path to Excel parameter file"
$sheetName = "DirPartyQuickCreateForm"
for ($i = $start; $i -lt $start + $nr; $i++ )
{
    $CustomerId = $i.ToString("000000000")
    Write-Host "customer : " $CustomerId
    UpdateCustomer $excelFilename $sheetName $CustomerId
    RunTestCase $excelFilename

Run a script that depends on data in Microsoft Dynamics 365
The following example uses an Open Data Protocol (OData) call to find the order status of a purchase order. If
the status isn't invoiced, you can, for example, call an RSAT test case that posts the invoice.
function Odata_Get {
    Param ( [string] $environment, [string] $cmd )
    $tenant = "your tenant"
    $creds = @{
        grant_type = "client_credentials"
        client_id = "your client application Id"
        client_secret = "your client secret"
        resource = $environment
    }
    $headers = $null
    $headers = @{
        Authorization = "Bearer " + $bearer.access_token
    }
    $Odata_cmd = $environment + '/data/' + $cmd
    return (Invoke-RestMethod -Uri $Odata_cmd -Method Get -Headers $headers -ContentType application/json )
}
function PurchaseOrderStatus {
    Param ( [string] $environment, [string] $purchaseOrderNumber )
    $cmd = 'PurchaseOrderHeaders?$filter=PurchaseOrderNumber eq '
    $cmd = $cmd + $'" + $purchaseOrderNumber + "'
    $response = Odata_Get -environment $environment -cmd $cmd
    return $response.value.PurchaseOrderStatus
}
$environment = "https://your environment"
$orderStatus = PurchaseOrderStatus -environment $environment -purchaseOrderNumber '000003'
if ($orderStatus -eq $null) { write-host 'doesn't exist'}
elseif ($orderStatus -ne 'invoiced') { RunTestcase "PostInvoice" }
The Regression suite automation tool (RSAT) uses privileged resources on the machine that it is running on. A user must be an administrator on the machine to run RSAT tests. This topic explains how to grant these privileged resources to users if you are using **RSAT version 2.2 or later**. The non-administrator user can run RSAT tests without being an administrator on the machine.

These instructions will not allow a non-administrator user to install RSAT. The instructions only enable using RSAT after it has been installed. This situation includes first-time use of RSAT where the Selenium framework is installed, or with new browser driver installation after updating browser versions. Those installation steps still require running RSAT with administrator privileges.

When RSAT is installed on a virtual machine (VM) that is shared by multiple users, then users can become blocked when multiple users run RSAT at the same time. For example, a user might hold resources while running tests cases, which then blocks access to other users. These instructions do not change that behavior.

### Enable non-administrator RSAT use

To enable non-administrator RSAT use, you need two PowerShell scripts and a new shortcut file. These files are in the RSAT installation folder in the subfolder named **Enable non admin**.

1. Open Windows PowerShell as Administrator.

2. Change the folder to **Enable non admin** in the RSAT installation folder. The installation folder is named according to the localized Windows running on the machine, for example `C:\Program Files (x86)\Regression Suite Automation Tool\Enable non admin`.

3. In the folder **Enable non admin** you will find these files:
4. The first file, **Enable-non-admin-mode.ps1** is a PowerShell script that enables non-administrator mode for the machine. Run this file once on each machine.

Run the script **Enable-non-admin-mode.ps1** directly from the *Enable non admin* folder, using these required parameters:

- **action**: (string) Option to enable or disable non-administrator mode. Valid values are *enable* and *disable*.
- **thumbprint**: (string) Certificate thumbprint. This value must be the same value that is specified in RSAT under General settings.

Here's an example:

```
.\Enable-non-admin-mode.ps1 "enable" "2305555DXXXXXXXXXXXXXXXXXXXXXX"
```

To get help, execute this command.

```
help .\Enable-non-admin-mode.ps1 -full
```

**IMPORTANT**

DO NOT remove or copy this PowerShell script from the *Enable non admin* folder. Run it only from this folder.

5. The second file, **Enable-non-admin-user.ps1** is a PowerShell script that enables non-administrator mode for a user. Run this script for each user that is going to use RSAT on the machine.

Run the script **Enable-non-admin-user.ps1** directly from the *Enable non admin* folder, using these required parameters:

- **action**: (string) Option to enable or disable non-administrator mode. Valid values are *enable* and *disable*.
- **thumbprint**: (string) Certificate thumbprint. This value must be the same value that is specified in RSAT under General settings.
- **user**: (string) The local username in the format `domain\userName`.

Here's an example:

```
.\Enable-non-admin-user.ps1 "enable" "TESTDOMAIN\testuser" "2305555DXXXXXXXXXXXXXXXXXXXXXX"
```

To get help, execute this command.

```
help .\Enable-non-admin-user.ps1 -full
```

**IMPORTANT**

DO NOT remove or copy this PowerShell script from the *Enable non admin* folder. Run it only from this folder.

7. Copy the shortcut file Regression Suite Automation Tool (Non admin).lnk to the user’s desktop. (The old shortcut calls a Visual Basic script that some users may not be allowed to execute. The new shortcut will call the executable file directly.)

**IMPORTANT**

DO NOT remove the old shortcut, because it is a shared file that is used by all users on the machine. If you remove the file, then it will disappear for all users. It is fine to remove the old shortcut if all users will be enabled to run as a non-administrator. However, the shortcut will reappear every time a new version of RSAT is installed.

8. When you start RSAT the first time, you must download and install the Selenium framework and the drivers that match the version of your browser. Users that are not administrators might not be able to download and install these components. In this case, RSAT might fail and generate exceptions. To download and install the components, run RSAT with administrator privileges to complete the installation. To run with administrator privileges, right-click the new shortcut Regression Suite Automation Tool (Non admin) and select Run as administrator. After the installation finishes, close RSAT and then have the user start RSAT again.

9. Use the new shortcut Regression Suite Automation Tool (Non admin) to start RSAT.

**Disable non-administrator RSAT use**

If you need to revert the machine back to run with administrator use, then run the PowerShell script Enable-non-admin-mode.ps1 with the action parameter set to disable.

```
.\Enable-non-admin-mode.ps1 "disable"
```

**Future versions of RSAT**

Currently, we are collecting feedback from users running RSAT with this non-administrator mode. In the future, we might change the installation process to automatically include the steps that enable non-administrator users.
This topic describes best practices and common use cases of the Regression suite automation tool (RSAT) and Task recorder.

Author test cases using the Task recorder

When you author task recordings for RSAT, follow these practices:

1. Make sure all your recordings start on the main dashboard.
2. Keep individual recordings short and focus on a business task performed by one user, like creating a sales order. This simplifies maintainability and reusability of test cases.
3. Chart controls are not supported. Any task recording actions related to charts will be ignored by RSAT during test case playback.
4. When creating a recording, make sure to select a tab header even if the tab is already open. For example, you can switch to another tab and then select the needed tab again to activate it before using a control on it. This will make your recording more reliable during test case playback.
5. RSAT cannot play back any test step that is not recognized by the task recorder. For example, you cannot upload a file from the local disk during play back of a test case.
6. RSAT cannot play back a page refresh step. Avoid refreshing a page while recording your test.

Best practices when using the Regression suite automation tool

1. Upon opening the tool for the first time, select Settings and ensure that you have all the needed settings.
2. Before installing a new version of the tool, it is recommended to close and uninstall the previous version.
3. When you install a new version of the tool, regenerate all test execution files.

It is not necessary to regenerate Microsoft Excel parameter files unless you want to take advantage of new features available in a newer format of parameter files.

4. For test parameters that need a unique value, for example, the product receipt number in the Product Receipt form or the invoice number in the Vendor Invoice form, use the RandBetween(a,b) Excel function to generate a unique number every time the test case is executed.

5. The default values in Excel come from the task recording. For Reference Group controls such as storage dimensions or tracking dimensions, it stores the key of the lookup instead of the value, for example, 2 instead of SiteWH. We recommend that you update these fields with the actual value in Excel so that the test is more robust and resilient to changes.
6. It is recommended to set the same locale for **Language** and **Date, time, and number format** settings of your environment prior to running RSAT. If these values are inconsistent, it may result in validation errors.

RSAT relies on Azure DevOps to store and manage test recording files (also known as task recordings). When RSAT loads a test plan from Azure DevOps, associated files are downloaded to the current **working directory** on your local computer. (This working directory is defined in RSAT settings.)

In version 1.200.42264.6 and later, it's easier to manage local recording files. You can make changes in Task recorder and then use RSAT to test them, without having to go through the Business process modeler (BPM) or Azure DevOps. When you use Task recorder, after you’ve finished authoring or modifying a recording, you can save it directly to your local disk as a developer recording.

Put the recording file under the working directory that is associated with the test case. For example, if your configured working directory is `C:\Users\<username>\Documents\RSAT`, put the recording file for test case 1234 under `C:\Users\<username>\Documents\RSAT\1234\attachments`. You must name the developer recording file **Recording.xml**. Alternatively, you can name the recording file `-Test Case Title-.xml`, where `-Test Case Title-` is the title of the test case in Azure DevOps.

The following illustration shows an example of a working directory folder structure. You can open the directory directly from RSAT by clicking the folder symbol.
Commit a recording file to Azure DevOps

Each test case has its own folder, which is named after the ID of the test case. Test case attachments (recording files, automation files, and Excel parameter files) are downloaded into an attachments folder. Here is an example.

```
P: Documents > 1396 > attachments
```

- Create_Sales_Order_1396_Base.cs
- Create_Sales_Order_1396_Base.dll
- Create_Sales_Order_1396_Base.xlsx
- Create_Sales_Order_1396_Base.xml
- Recording.xml

The generatorLogs directory contains log files. It doesn’t contain any files that users can modify. You can ignore this directory unless RSAT support explicitly asks you to provide log files from it.

**Commit a recording file to Azure DevOps**

After a recording has been tested and finalized, use RSAT to upload it and commit it to Azure DevOps. The upload button has two options: *Upload automation files* and *Upload recording file*. The second option uploads only your recording file to Azure DevOps.

**NOTE**

If you’re using a version of RSAT that is earlier than 1.200.37255.0, and you upgrade to the latest version, you must reload your test cases from Azure DevOps to download them into the correct directory. Otherwise, RSAT will fail, and you will receive a "File not found" error.

If you’re working across several DevOps projects, we recommend that you use a different working directory for each project. Otherwise, attachment files from multiple projects can become commingled in the same directory structure.

Modify (Edit) a Task recording

If you want to modify an existing task recording, note these best practices.

In the web client, open the Task recorder pane and start editing the recording using the *Edit Recording* option.
When you've finished editing the recording, play it back in the client, and verify that all the steps work correctly. Playback is required.

After you've finished playing back an edited recording, save it. It's then ready to be used by RSAT.

Copy test cases in Azure DevOps

As you are building your test suites in Azure DevOps, it is handy and common to duplicate test cases along with their attachments. If a copied test case contains an existing Excel parameter file attached, RSAT cannot execute it without manual edits to the Excel file. The **Test Case ID** in the Excel parameter file must match the Azure DevOps test case ID. You will need to edit all copied Excel parameter files. In the following image, the Excel file is associated with Test Case number 53 in Azure DevOps.

As of RSAT version 1.210, this process is easier. To automatically fix all occurrences of a mismatch, select the desired test cases in the grid, and then select **Resolve test case ID mismatch** in the **New** menu.
While the functional validation of an ERP application can’t be fully data agnostic, there are multiple phases and approaches for testing. These testing phases include:

- **SysTest framework**
  - The SysTest framework is reliable for writing unit tests. Because unit tests are generally testing a method or function, they should always be data agnostic and dependent only on the input data that is provided as part of the test.

- **ATL framework**
  - Microsoft has an ATL framework that is an abstraction on the SysTest framework and makes functional test writing much more simple and reliable. This framework should be used for writing component tests or simple integration tests.

- **Regression Suite Automation Tool (RSAT)**
  - The RSAT is used for integration tests and business cycle tests. The business cycle tests, also called the regression validation tests, are dependent on existing data. However, these tests can become data agnostic if you consider additional factors.

  - Where unit tests and component tests are low level and can fully be data agnostic (not dependent on existing dataset), the business cycle or regression validation tests are dependent on some existing data. This data includes setup, configuration settings (parameters), and master data (customer, vendors, items, etc.), but never transaction data. Make sure that during the test, if any of these are being changed, that they are reverted back as part of the final test.
  - Select master data based on certain criteria instead of selecting a particular record. For example, if you
want to select an item based on its dimension values and stock availability, filter the product list with those values, select the first item, and copy the number to be used for future tests. If it's a simple master data line such as customer, vendor, or item, it can be created as part of the automation and used in future tests through chaining.

- Enter the unique identifiers, such as invoice numbers, through the number sequence or by using Microsoft Excel functions such as =TEXT(NOW(),"yyyymmddhhmm"). This function will provide a unique number every minute, which allows you to track when the action happened. This can be used for variables such as product receipt numbers and vendor invoice numbers. These tests continue to work on the same database again and again, without requiring any restoration.

- Always set the **Edit mode** of the environment to **Read** or **Edit** as the first test case because the **default option is Auto**. The **Auto** options always use the previous setting and can cause unreliable tests.

- Only validate after you filter on a particular transaction instead of generic validation. For example, for the number of records, filter for the transaction number or the transaction date so that the validation excludes all other transactions.

- If you are checking a customer balance or budget check, save the value first and then add your transaction value to validate the expected result instead of validating a fixed expected value.
This topic contains information about how to troubleshoot the Regression suite automation tool (RSAT).

**Playback logs**

To troubleshoot issues that happen during playback of a test case, open the developer error log located at `[RSAT working directory]\[test case ID]\playback\[TestName]Log.txt`. The RSAT working directory is the directory specified in the RSAT settings dialog. Analyze the error message to determine the possible cause of a failure.

**NOTE**

For RSAT versions prior to 1.210, the log is located at C:\Users\[YourUserName]\AppData\Roaming\regressionTool\playback\[TestName]Log.txt.

**Generator logs**

To troubleshoot errors when generating test execution and parameter files, enable generator logs.

Open the `Microsoft.Dynamics.RegressionSuite.WindowsApp.exe.config` file under the RSAT installation folder (for example, C:\Program Files (x86)\Regression Suite Automation Tool), and change the value in the following element from `false` to `true`.

```xml
<add key="LogGeneration" value="true" />
```

After test execution files are generated, you can find the log file under `[RSAT working directory]\[test case ID]\generatorLogs`.

**NOTE**

For RSAT versions prior to 1.210, the logs are generated under C:\Users\[Username]\AppData\Roaming\regressionTool\generatorLogs.

**Authentication certificate and installation**

- The authentication certificate must be created and installed by an administrator on the same computer where RSAT is installed. If it is not created by an admin, you will encounter the following error message when you try to run a test case.

  Cannot access Finance and Operations environment. Verify your settings and make sure the environment is available.

- If you have used a previous version of RSAT on the same computer, close it and uninstall it before installing a new version.

**Screen resolution when using Internet Explorer**
If you have selected Internet Explorer as your browser, your desktop resolution should be set to 100% to run the tests successfully. To change the settings, use Windows Display settings > Scale and layout, as shown in the following image:

**Scale and layout**

Change the size of text, apps, and other items

100%

---

**Test playback errors**

**SOAP or HTTP request errors**

If you are testing against a Standard Acceptance Test Sandbox environment (Tier2) or any other multi-box environment, and you may receive one of the following errors when you run a test.

There was no endpoint listening at https://<yourURL>/soap.sandbox.operations.dynamics.com/Services/AxUserManagement/Service.svc/ws2007FedHttp that could accept the message. This is often caused by an incorrect address or SOAP action.

An error occurred while making the HTTP request to <Hostname>/Services/AxUserManagement/Service.svc/ws2007FedHttp. This could be due to the fact that the server certificate is not configured properly with HTTP.SYS in the HTTPS case. This could also be caused by a mismatch of the security binding between the client and the server.

Assuming that you have specified the correct SOAP hostname in the RSAT settings dialog box, run the following PowerShell scripts on your client computer where the test tool is installed.

```powershell
Set-ItemProperty HKLM:\SOFTWARE\Microsoft\.NETFramework\v4.0.30319 -Name SchUseStrongCrypto -Value 1 -Type dword -Force -Confirm:$false
if ((Test-Path HKLM:\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\v4.0.30319))  { Set-ItemProperty HKLM:\SOFTWARE\Wow6432Node\Microsoft\.NETFramework\v4.0.30319 -Name SchUseStrongCrypto -Value 1 -Type dword -Force -Confirm:$false}
```

You can also manually set the registry keys.

**Cannot enumerate AX users error**

You may receive the following error when running a test case, or the error details may contain the following messages.

```plaintext
<Message>Could not enumerate AX users</Message> (InnerError)
```

To resolve this error, verify the **Admin user name** specified in the RSAT settings dialog box. The **Admin user**
Unsecured fault exception

If a test case inconsistently fails with the following error, this usually indicates an incomplete configuration of the authentication thumbprints on the AOS virtual machines.

```
<Message>An unsecured or incorrectly secured fault was received from the other party. See the inner FaultException for the fault code and detail.</Message>
<Message>At least one security token in the message could not be validated.</Message>
```

Typically, this error happens when the test environment has not been configured to trust the certificate that RSAT is using for authentication. (The certificate is identified by the thumbprint specified in your RSAT settings.) For example, the thumbprint could be missing in the wif.config file on the AOS virtual machine of the test environment. If you are running against a standard acceptance test environment (Tier 2 or higher), you might not have configured the authentication thumbprint on all of the AOS virtual machines. Make sure you properly add the thumbprint to the wif.config file on all of the AOS machines. For more information, see Configure the test environment to trust the connection.

We have also seen this error when there is a mismatch between the UTC time between the client computer (where RSAT is installed) and the Finance and Operations environment. This is a rare case and only happens if your administrator has incorrectly configured the UTC time. The client computer and Finance and Operations environment can be on different time zones; however, the UTC time on both environments must match because the authentication mechanism relies on this comparison.

Google Chrome Browser

The Google Chrome browser may not work with the Regression suite automation tool due to your Active Directory security settings. In this case, change your RSAT settings to use the new Microsoft Edge or Internet Explorer.

Validating blank dates

If your test case requires validation that a certain control of type Date/Time is blank, you can insert the following value into the Excel cell corresponding to this control: “01/01/1900”.

Azure DevOps connectivity

You might you see this error when you select the desired Azure DevOps project in RSAT settings: "The structure path <iteration path> is not valid. Verify your settings and try again". To resolve this error, open the project in Azure DevOps and navigate to the Test Plans. Verify the iteration path defined for each test plan. If the iteration path is similar to what is shown in the error, remove the existing iteration path and add a new one for the test plan and save.
Lifecycle Services (LCS) solution packages for Microsoft AppSource are partner-designed and developed solutions that can be automatically deployed on Microsoft Azure to deliver an end-to-end solution, using industry and vertical-specific content.

This topic points to resources that will help you understand the requirements for creating LCS solutions for Microsoft AppSource. The requirements for creating an LCS solution package fall into the following groups.

- App validation
- Code migration
- Database backup and Data packages
- Business process models
- Methodologies
- Marketing
This topic explains how to create and modify methodologies in Microsoft Dynamics Lifecycle Services (LCS). It also provides information about the requirements for methodologies.

Methodology requirements

The first two phases of your methodology are the Learn and Consume phases from the LCS Solutions Consumption methodology.

During the Learn phase, your product description must be aligned with your business process library, the descriptions or summaries in your marketing material, and the functionality that is supported in the current version of your solution. The Learn phase includes the following tasks:

- **Product description** – Take advantage of your marketing description by adding it to the LCS methodology.
- **Get an overview** – Include content for your solution, such as information about the features and architecture.
- **How to get help** – Include numbers, contacts, or direct links to your company’s website, for people who help build and maintain the solution.

The Consume phase is optional. It includes tasks that are required in order to complete Conference room pilot 1 (CRP1).

After the Learn and Consume phases, you can add any other steps that are required in order to implement your solution. You can either modify the phases and tasks so that they are aligned with your solution, or use your company’s implementation methodology.

Create a new methodology

1. On the LCS home page, select the **Manage methodologies** tile.
2. Select the **New methodology** button (the plus sign [+]).
3. Set values for the fields, and then select **Confirm**.
4. Create phases and tasks.
5. Add any linked tools and resources that are required.

Edit a methodology

1. On the LCS home page, select the **Manage methodologies** tile.
2. Select the methodology to edit.
3. Select the **Edit methodology** button (the pencil symbol), and edit the methodology.

Edit a project's methodology

Follow these steps to edit a methodology in a specific project only.

1. On the project's home page, select the ellipsis (...) button above the project phases, and then select **Edit methodology**.
2. Edit the phases and tasks.
3. Edit the linked tools and resources, if any changes are required.
Change a project’s methodology

1. On the project’s home page, click the ellipsis (…) button above the project phases, and then click Change methodology.

2. In the dialog box that appears, set the Do you want to keep the existing phases and tasks? option. If you set this option to Yes, the phases and tasks from the methodology that you select in step 3 are added to the end of the current methodology. If you set the option to No, the current methodology is replaced with the methodology that you select in step 3.

3. Select a methodology to use with your project.

4. Select Confirm.

Requirements for publishing apps on AppSource
Create a business process library

There are two ways to create a BPM library. You can create a new library that has no lines or task recordings, or you can copy an existing library.

1. In Microsoft Dynamics Lifecycle Services (LCS), open a project, scroll to the right until you see the **More tools** section, and then select the **Business process modeler** tile. The **Business process libraries** page that appears has three sections, one for each type of library:
   - **My libraries** – Business processes that users have created or added.
   - **Corporate libraries** – Custom business processes that someone in your organization has uploaded.
   - **Global libraries** – Cross-industry standard business processes.

2. To create a new library, right-click any library, and then, in the lower-left corner of the window, select **Create**. To copy an existing library, right-click that library, and then, in the lower-left corner of the window, select **Copy**.
Update, publish, or delete a business process library

You can change the name or description of a library, publish a library so that other people in your organization can view it, or delete a library.

- On the **Business process libraries** page, right-click the library to update, publish, or delete. Then, in the lower-left corner of the window, select **Edit**, **Publish**, or **Delete**.
  - **Edit** lets you change the name and description of the library.
  - **Publish** creates a copy of the library under **Corporate libraries**. This library will be available to everyone in your organization.
  - **Delete** deletes the library and any information that is stored in it.

Modify a business process library

Follow these steps to change or update the business process lines or hierarchy in your business process library.

1. Select and open the library to update.
2. In the left pane, under **Core views**, select **Author and edit**.
3. Follow one or more of these steps to make the required changes:
   - To rearrange the hierarchy of the business process lines, drag the processes in the hierarchy.
   - To delete a node, select a business process in the center pane, and then select **Delete** in the right pane.
   - To create a new node, drag the **New Business Process** flag at the top of the center pane to the place in the hierarchy where the new node should appear.
To import business processes from existing business process libraries, follow these steps:

a. Select Import in the center pane.

b. On the right side of the page that appears, select the library to import business processes from.

c. Drag the required business processes into the hierarchy on the left side of the page.

View and modify task recordings in a business process library

1. Open the library that you want to work in.

2. Navigate to the business process line that has a task recording associated with it, and select the link.

3. Drag the tiles under Activities to manually modify the flow chart.

4. To upload a Microsoft Visio diagram of the modified flow chart, select the Visio tab.

Structure a business process library

There are two sections in business process libraries: Core Business Processes and Support Processes. The Core Business Processes section should include all custom business processes for your solution. All customizations and functionality should be covered in end-to-end scenarios. Task recordings should be created for all processes in this section. Import American Productivity & Quality Center (APQC) processes that are relevant to your solution into the Support Processes section. This section should not include any custom business processes. You don't have to create task recordings for processes in this section. Your business process library should be aligned with the descriptions and summaries in your methodology and your marketing material.

Create a task recording and associate it with a business process

Task recordings should be created in an environment that has your custom data and customizations. For reference information about Task recorder, see Task recorder resources.

Create a task recording

1. In your application, select the Settings button in the upper-right corner, and then select Task recorder.

2. Select Create recording.

3. Enter a name and description for the recording.

4. Perform the task that you want to record.
5. When you’ve completed the task, select **Stop**.

6. If you want to upload your new task recording to LCS, continue to the next section. To save your recording to your local computer or convert the recording to a Microsoft Word document, select the appropriate option.

**Associate a task recording with a business process**

1. Select **Save to LCS**.
2. Select a business process library.
3. Select the business process line to associate with the recording.
4. Select **OK**.

You can now view the task recording in the business process library in LCS.

**Set up and use task guides**

Task recordings can be played as task guides. Task guides are used to guide users through the steps for completing business processes. Before you set up and use task guides, create task recordings, and save them to a business process library in LCS.

**Set up task guides**

1. In your application, select **System administration > Setup > System parameters**.
2. On the **Help** tab, select the LCS project where the business process library that you want to work with is stored.
3. Select the business process libraries that have the task recordings that you want to play as task guides.
4. Adjust the order of the business process libraries as you require. The order of the business process libraries determines the order that the task guides appear in. Therefore, the task guides for the first business process library appear first when a user uses the task guide functionality.

**Use task guides**

1. In your application, open the page where you want to run the task guide.
2. In the upper-right corner, select the **Settings** button, and then select **Task recorder**.
3. Select a task guide.
4. Select **Start Task guide**.
5. Follow the steps in the task guide. If you select **Unlock**, you can work without following the task guide.
6. When you’ve finished, select **Stop Task guide**.

**Additional resources**

Requirements for publishing apps on AppSource](lcs-solutions-app-source.md)
To complete your solution package, the first step is to upgrade your code by using the best practices in Migrate and Create Finance and Operations Apps Solutions in Microsoft Dynamics Lifecycle Services (LCS). After that step is completed, you must run the Customization Analysis Report (CAR). This report analyzes your customization and extension models, and runs a predefined set of best practice rules.

To generate the CAR, run the following command on a development environment.

```bash
xppbp.exe -metadata=<local packages folder> -all -model=<ModelName> -xmlLog=C:\BPCheckLogcd.xml -module=<PackageName> -car=<reportlocation>
```

Here is an example of this command.

```bash
xppbp.exe -metadata=C:\Packages -all -model=MyAppSuiteCustomizations -xmlLog=C:\temp\BPCheckLogcd.xml -module=ApplicationSuite -car=c:\temp\CARreport.xlsx
```

The xppbp.exe file is located in `c:\packages\bin` or `I:\AosService\Packages\LocalDirectory\bin`. You must resolve any warnings or errors that appear on the Issues tab of the report. You must then submit a copy of the CAR to Microsoft before your validation meeting. For more information, see Customization Analysis Report (CAR). For information about issues and exceptions, see the Customization Analysis Report: Exceptions and known issues post on the Dynamics 365 Community blog.

**Extensibility**

In Microsoft Dynamics 365 for Finance and Operations version 8.0 (April 2018), all product models are sealed. Therefore, only extension-based customizations are currently supported. For more information about extensibility, see Extensibility.

The first step in completing your solution package is to upgrade your code using the best practices in Migrate and Create Finance and Operations Apps Solutions in LCS. After this step is complete, you must run the Customization Analysis report. This report analyzes your customization and extension models, and runs a predefined set of best practice rules.

To generate the Customization Analysis report (CAR), run the following command on a development environment.

```bash
xppbp.exe -metadata=<local packages folder> -all -model=<ModelName> -xmlLog=C:\BPCheckLogcd.xml -module=<PackageName> -car=<reportlocation>
```

Here's an example of how this command might look.

```bash
xppbp.exe -metadata=C:\Packages -all -model=MyAppSuiteCustomizations -xmlLog=C:\temp\BPCheckLogcd.xml -module=ApplicationSuite -car=c:\temp\CARreport.xlsx
```

The xppbp.exe file is located in `c:\packages\bin` or `I:\AosService\Packages\LocalDirectory\bin`. Any warnings or
errors that appear on the Issues tab of the report must be resolved. A copy of the CAR report must be submitted to Microsoft prior to your validation meeting. For more information, see Customization Analysis Report (CAR) or refer to the Dynamics Community blog for issues and exceptions.

Requirements for publishing apps on AppSource

Develop and customize home page
This topic provides information about the requirements that are used to verify that custom code meets Microsoft guidelines, and that a solution package can be successfully bundled and delivered in a Finance and Operations apps environment.

Microsoft requires specific reviews in order to validate the following requirements:

- A partner’s custom code meets Microsoft guidelines.
- A Microsoft Dynamics Lifecycle Services (LCS) solution package can be successfully bundled and delivered.
- Core independent software vendor (ISV) business scenarios can be transacted.

Currently, partners must demonstrate that these requirements have been met by doing test deployments and then sharing the results with Microsoft. No code will be deployed on a customer environment that Microsoft hasn’t validated. Partners must complete the following curation artifacts and tests:

- Code analysis report (CAR)
- Business process modeler (BPM)/test scripts
- Business database backup
- Project name and description
- Data packages
- Methodology
- Binaries (optional)
- Deployable packages
- Models (code and tests)
- Marketing content

### Curation meeting

The following table describes the steps that must be completed before the validation meeting.

<table>
<thead>
<tr>
<th>PHASE</th>
<th>STEP</th>
<th>ACTIVITY</th>
<th>PROCESS STEPS</th>
<th>SUCCESS CRITERIA</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Validate code.</td>
<td>Run all customer model files by using the CAR tool, and then generate the report.</td>
<td>Successfully create a CAR without any localization, accessibility, performance, or security issues.</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Verify user experience (UX) guidelines.</td>
<td>Follow UX guidelines to implement the workspace correctly.</td>
<td>Reference best practice information in the Migrate and Create methodology section of LCS.</td>
</tr>
<tr>
<td>PHASE</td>

<td>-----------------</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>Validate the solution package in LCS.</td>
<td>Create a solution package in LCS that includes all the required artifacts.</td>
<td>A solution package that has all the required artifacts has been published in LCS, and a globally unique identifier (GUID) has been created for the solution.</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>Deploy an environment.</td>
<td>Deploy a standard environment that has partner code, based on the package contents (code, binaries, and configuration).</td>
<td>Successfully deploy at least one Finance and Operations environment without any errors. The environment configuration (including components and the configuration) is the same as the partner’s reference environment. A user can successfully sign in to this environment without any errors.</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>Configure and deploy data.</td>
<td>Deploy partner-supplied data in the environment without any errors.</td>
<td>Demonstrate that partner-supplied master and reference data was successfully pushed into the environment without any errors.</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>Do a sanity check.</td>
<td>After data has been loaded into the environment, users should be able to complete business transactions (as defined in the scope of the solution).</td>
<td>Users can sign in to the data-loaded environment without any errors. Business transactions can be completed, as defined in the package scope, without any errors.</td>
</tr>
</tbody>
</table>

**Detailed curation requirements**

The following table provides more information about each curation requirement.

<table>
<thead>
<tr>
<th>REQUIREMENT</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAR</td>
<td>All major issues that the CAR highlights should be addressed after you upgrade. The CAR must be submitted to Microsoft before the validation meeting.</td>
</tr>
<tr>
<td>BPM/test scripts</td>
<td>All task recordings should be completed for the industry vertical that the solution package is designed for and should include end-to-end scenarios.</td>
</tr>
<tr>
<td>REQUIREMENT</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Business database backup</td>
<td>A business database of your upgraded environment and best practice configurations should be loaded into the Asset library in LCS.</td>
</tr>
<tr>
<td>Project name and description</td>
<td>The project name and description should be incorporated into the beginning of the implementation methodology for the solution package.</td>
</tr>
<tr>
<td>Data packages</td>
<td>All data packages should be loaded into LCS before the validation meeting. Create data entities for any additional custom fields or tables for your custom functional features. You should be able to modify the data packages and load them into an empty environment, and then consume the data packages in Data Management Framework.</td>
</tr>
<tr>
<td>Methodology</td>
<td>The methodology should incorporate an overview of the product. A guided experience to Conference Room Pilot 1 (CRP1) and any other implementation methodology that is specifically tailored to your solution are optional.</td>
</tr>
<tr>
<td>Binaries (optional)</td>
<td>Incorporate any required binary files.</td>
</tr>
<tr>
<td>Deployable packages</td>
<td>Incorporate the deployable packages that are required in order to bring your custom features and functionality into your environment.</td>
</tr>
<tr>
<td>Models (code and tests)</td>
<td>Incorporate any model files that are required for your solution.</td>
</tr>
<tr>
<td>Marketing content</td>
<td>Add your marketing content, such as logos, descriptions, and screen shots of your solution package. The solution logo should be app-specific and should not include your company name. The description should be aligned with your custom business processes.</td>
</tr>
</tbody>
</table>

**Update and maintenance requirements**

If you have a curated solution that is published on AppSource, you must keep the solution up to date. After each major Spring and Fall release, you will have eight weeks to upgrade your code. You must update and test the following artifacts:

- CAR
- Models (code and tests)
- Deployable packages
- BPM/test scripts
- Data packages
- Business database backup

**Maintenance process steps**

<table>
<thead>
<tr>
<th>PHASE</th>
<th>NUMBER</th>

<td>Validate customer code.</td>
<td>Run all customer model files by using the CAR tool, and generate the report.</td>
<td>Successfully create a CAR without any localization, accessibility, performance, or security issues. All major issues that the CAR highlights should be addressed after you've upgraded to the latest major release. The CAR must be submitted to Microsoft within eight weeks after each major Spring and Fall release.</td>
</tr>
</tbody>
</table>

### Additional resources

[Requirements for publishing apps on AppSource](#)
A data package for a Dynamics 365 Finance and Operations app can consist of one or many data entities. A typical data package consists of a group of entities for a specific task, process, or function. For example, the data entities that are required for general ledger setup might be part of one data package. The format of a data package is a compressed file that contains a package manifest, a package header, and any additional files for the data entities that are included.

Before you create your data package, plan out what it should include. In this way, you help guarantee that the correct entities, entity sequence, and fields are included. You create a data package by using the Data management workspace in your application. Follow these steps to create a data package.

1. In the application, select **System administration** > **Workspaces** > **Data Management IT**.
2. Select the **Export** tile, and then, in the **Name** field, enter **Data project**.
3. In the **Target data format** field, select the format for the export. The data formats that are available include comma-separated value (CSV) format and Microsoft Excel format.
4. In the **Entity name** field, enter or select an entity. You can add multiple entities, but you must add each entity separately.
5. In the **Select fields** field, select a field setting, and then click **Add entity** to add the entity to the project.
6. Repeat steps 4 and 5 to add more entities to the project. **Note:** As you add each entity to the project, a tile appears that contains the entity's name and two buttons: **View map** and **Filter**. To automatically create a data package when you export the data project, set the **Generate data package** option to **Yes**. If you don't set this option, you can create a data package at the time of export.
7. On the Action Pane, click **Export**.
8. Click **Download**. The package is saved to the **Downloads** folder of the computer where the browser session is running. When you work with data packages, you must plan for and consider any prerequisites for the entities that will be included in the packages. For example, the customer groups are required in order to create customers. Therefore, you should either import the customer groups into a package before you import customers, or sequence customer groups within a data package that will be completed before customers are imported. For example, in the following illustration, sequencing is set within the data package. As you can see, the Customer groups entity and Customers entity are part of the Customers data project.
To automatically create a data package when you export the data project, set the **Generate data package** option to **Yes**. If you don't set this option, you can create a data package at the time of export.

9. On the Action Pane, select **Export**.

10. Select **Download**. The package is saved to the **Downloads** folder of the computer where the browser session is running. When you work with data packages, you must plan for and consider any prerequisites for the entities that will be included in the packages. For example, customer groups are required in order to create customers. Therefore, you should either import the customer groups into a package before you import customers, or sequence customer groups within a data package that will be completed before customers are imported. For example, in the following illustration, sequencing is set in the data package. As you can see, the Customer groups entity and Customers entity are part of the Customers data project.

11. On the Action Pane, select **Entity sequence** to open the **Definition group entity sequence** page. Based on the current setup, the Customer groups entity and Customers entity are run at the same level. However, this sequence might not be ideal.
12. To create a better sequence, select the **Customers** entity, and then update the value of the **Execution unit** field from 1 to 2. This change helps guarantee that customer groups are imported before the Customers entity is run.

Microsoft Dynamics Lifecycle Services (LCS) contains multiple base data packages that you can use to reduce the implementation time. These packages contain the elements that are required in each module/area in order to meet the minimum requirements. For advanced business processes, you might have to add more entities to the list of packages. The data packages that Microsoft publishes on LCS use a numbering sequence that is based on the module, data type, and sequence. Here is an example:

- **Module/area number**

<table>
<thead>
<tr>
<th>Module</th>
<th>Module Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>System administration</td>
<td>01</td>
</tr>
<tr>
<td>General ledger</td>
<td>03</td>
</tr>
<tr>
<td>Public Sector</td>
<td>04</td>
</tr>
<tr>
<td>HRM</td>
<td>05</td>
</tr>
<tr>
<td>Accounts payable</td>
<td>10</td>
</tr>
<tr>
<td>Accounts receivable</td>
<td>11</td>
</tr>
<tr>
<td>Budgeting</td>
<td>12</td>
</tr>
<tr>
<td>Cash and bank management</td>
<td>13</td>
</tr>
<tr>
<td>Compliance and internal controls</td>
<td>14</td>
</tr>
<tr>
<td>Cost accounting</td>
<td>15</td>
</tr>
<tr>
<td>Fixed assets</td>
<td>16</td>
</tr>
<tr>
<td>Inventory management</td>
<td>19</td>
</tr>
<tr>
<td>Master planning</td>
<td>20</td>
</tr>
<tr>
<td>Organization administration</td>
<td>21</td>
</tr>
<tr>
<td>Payroll</td>
<td>22</td>
</tr>
<tr>
<td>Procurement and sourcing</td>
<td>23</td>
</tr>
<tr>
<td>Product information management</td>
<td>24</td>
</tr>
<tr>
<td>Production control</td>
<td>25</td>
</tr>
<tr>
<td>Project management and accounting</td>
<td>26</td>
</tr>
<tr>
<td>Retail</td>
<td>27</td>
</tr>
<tr>
<td>Sales and marketing</td>
<td>28</td>
</tr>
<tr>
<td>Service management</td>
<td>29</td>
</tr>
<tr>
<td>Trade allowance management</td>
<td>31</td>
</tr>
<tr>
<td>Transportation management</td>
<td>32</td>
</tr>
<tr>
<td>Travel and expense</td>
<td>33</td>
</tr>
<tr>
<td>Warehouse management</td>
<td>34</td>
</tr>
</tbody>
</table>

- **Data type numbering**

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Data Type Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Setup</td>
<td>1</td>
</tr>
<tr>
<td>Master</td>
<td>4</td>
</tr>
<tr>
<td>Transaction</td>
<td>8</td>
</tr>
</tbody>
</table>

- **Numbering format**
The names of data packages include the numbering format, which is followed by the module abbreviation and then a description. For example, the following illustration shows the General ledger data packages.

<table>
<thead>
<tr>
<th>Numbering Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Module #. Data Type Reference .001 (Sequence Number)</td>
</tr>
<tr>
<td>01.1.001</td>
</tr>
<tr>
<td>01.1.002</td>
</tr>
<tr>
<td>01.4.001</td>
</tr>
<tr>
<td>01.4.002</td>
</tr>
<tr>
<td>03.1.001</td>
</tr>
</tbody>
</table>

Process data packages

A process data package (PDP) consolidates Data import/export framework (DIXF) data packages into a unified bundle. The PDP is then used to configure a business process or a group of business processes in one business process library. Together, DIXF data packages, dependencies between those packages, and business processes that require the packages for their configuration make up a PDP. This section describes how to create a PDP for your LCS solution package. To create a PDP, you must have the following items and knowledge:

- An implementation business process library for the solution in your working LCS project.
- DIXF data packages that have configurations that follow best practices. These packages should include master and reference data for the whole solution.
- An understanding of the dependencies between the data in the packages.
- An understanding of the data dependencies between the data packages.

Follow these steps to create a PDP.

1. In LCS, select the Asset library tile.
2. Select Data package as the asset type, and then select the plus sign (+) to add a data package.

Follow these steps to consolidate the data packages that you uploaded to LCS into a single PDP.

1. In LCS, select the Asset library tile.
2. Select Process data package as the asset type, and then select the plus sign (+) to add a PDP.
3. Enter a name and description for the PDP, and then select Confirm.
4. For step 1, “Add business process library,” select the implementation business process library that your solution is built for, and then select Continue.
5. For step 2, “Add data packages,” select Edit, and then add the data packages that are required in order to configure the system and enable the business process library transactions to be run. When you've finished adding data packages, select Select. The order in which data packages in the PDP are loaded into the system might be important. For example, before a chart of accounts (COA) can be loaded, the legal entity setup and currencies are required. Those data entities are in 01.1.002 System Setup. Therefore, 03.1.1001 COA Setup depends on 01.1.002 System Setup. In the next step, you must make a note of this dependency.
6. For step 3, “Add data package dependencies,” select a data package, and then select Edit. Select the dependent data packages that must be loaded into your target environment before the data package that you selected, and then select Select.
7. For step 4, “Associate business process to data packages,” select the business process that should be used to configure the process nodes.
Consume a PDP

**IMPORTANT**

For the PDP consumption requirement, you have the option to consume data packages directly via the Data Management Framework in your environment. However, note that only the consumption of data packages via the LCS PDP tool is optional. You must still create the PDP and upload it to your Asset library.

The Consume flow lets you review a business process, and apply the configuration and data that are required in order to implement the business process in your environment. To consume PDPs, you must have the following items:

- An implementation business process library for the solution in your working LCS project
- PDPs
- A target environment that includes an existing legal entity

Follow these steps to consume the PDP:

1. In LCS, select the Asset library tile.
2. Select Process data packages as the asset type, and then select Consume.
3. The Consume process data package page shows a list of the existing PDP assets. Select the plus sign (+) to create a new Consume PDP.
4. Enter a name for the Consume PDP, select the PDP that you created and saved in the Asset library, select a target environment, and then select Create.
5. The Consume PDP that you created appears in the list of PDP assets. Select the package.

**NOTE**

The asset that you created can be consumed only in the target environment that was linked to it.

Review and approve BPMs

- For step 1, “Review business process,” review the business process models (BPMs), and then select Mark as reviewed. The review status is updated for all dependent processes, and a green bar appears to the right of them. The Reviewed by and Completed on fields are also updated for each business process.

Review and approve data packages that are associated with a BPM

1. In the BPM library that you just reviewed, in the left pane, select Approve the data packages.
2. Select the business process that is associated with the data packages. The data packages appear in the right pane, under Process details. In the right pane, select Review and Approve.
3. On the **Consume process data package** page, select a package, and then select **Download** to download the data package. Save the package locally. You can then update the data files in the data package with data that is specific to your target environment. When you’ve finished updating the data files, select **Upload data package** to upload your changes.

4. After the data package has been updated and completed, select **Approve**. The status is changed to **Approved**. You can approve as many data packages as you require.

5. Select the **Back** button, select 2 **Approve the data packages** again, and then select the business process. You should see the **Approved** status in the right pane, under **Process details** > **Dependent packages**.

**Apply a process data package**

1. In the BPM library, in the left pane, select 3 **Apply process data package**.
2. Select the business process, and then, in the right pane, select **Apply Data Packages**.
3. On the **Consume process data package** page, select a package, and then select **Apply**.
4. Select the destination company in the target environment that is linked to the PDP, and then select **Apply**.

   - For step 1, ”Review business process,” review the business process models (BPMs), and then click **Mark as reviewed**. The review status is updated for all dependent processes, and a green bar appears to the right of them. The **Reviewed by** and **Completed on** fields are also updated for each business process.

**Review and approve data packages that are associated with a BPM**

1. In the BPM library that you just reviewed, click 2 **Approve the data packages** in the left pane.
2. Select the business process that is associated with the data packages. The data packages appear in the right pane, under **Process details**. Click **Review and Approve** in the right pane.
3. On the **Consume process data package** page, select a package, and then click **Download** to download the data package. Save the package locally. You can then update the data files in the data package with data that is specific to your target environment. When you’ve finished updating the data files, click **Upload data package** to upload your changes.
4. After the data package has been updated and completed, click **Approve**. The status is changed to **Approved**. You can approve as many data packages as necessary.
5. Click the **Back** button, click 2 **Approve the data packages** again, and then select the business process. You should see the **Approved** status in the right pane, under **Process details** > **Dependent packages**.

**Apply a process data package**

1. In the BPM library, click 3 **Apply process data package** in the left pane.
2. Select the business process, and then, in the right pane, click **Apply Data Packages**.
3. On the **Consume process data package** page, select a package, and then click **Apply**.
4. Select the destination company in the target environment that is linked to the PDP, and then click **Apply**.

**View the data package history**

- On the **Consume process data package** page, select a package, and then select **History**. You can review the status of the data package. The available information includes the target environment, company, package
name, start and end times, status by data entity, and overall status of the data package. To see the details of any errors that occurred, you can sign in to the target environment.

**Additional resources**

Requirements for publishing apps on AppSource
A backup of the Finance and Operations apps database is required for your Microsoft Dynamics Lifecycle Services (LCS) solution package. When you back up the database, you must include the master, reference, and transactional data that is specific to your solution and industry. This data will be used for your pre-sales demo deployments.

On demo or development environments, the database is typically named AXDBRain. Your database backup should be no larger than 15 gigabytes (GB). Otherwise, a time-out error might occur when you try to upload the database to the Asset library in LCS.

To compress your database backup, in Microsoft SQL Server Management Studio, on the Back Up Database page, in the Set backup compression field, select Compress backup.

On demo or development environments, the database is typically called AXDBRain. Your database backup should be no larger than 15 gigabytes (GB). If your database is larger, a time-out error may occur when you try to upload the database to the Asset library in Lifecycle Services (LCS).

To compress your database backup, in SQL Server Management Studio, on the Back Up Database page, in the Set backup compression field, select Compress backup.

Requirements for publishing apps on AppSource
Local and regional deployments

If your government regulations require data to be stored differently or serviced differently than is required for other countries/regions, there might be country/region requirements you must consider during deployment. Consider the following resources that might be relevant to you:

Finance and Operations apps operated by 21Vianet in China

Localization and regulatory features

Finance and Operations apps include functionality for the country/regions documented in the Product localization and translation availability guide. This functionality is enabled based on the primary address of the active legal entity.

This topic includes lists of resources that can help you do the following:

- Learn more about developing country/region-specific solutions.
- Get country/region specific updates.
- Submit and review regulatory alerts.
- Learn how to use country/region specific functionality.

Developing localized solutions

The following resources provides guidance and information that can help developers and ISVs who are creating country/region-specific customizations or are creating a solution for a country that Microsoft does not support.

- Separation of localization models
- Apply country/region context
- Regulatory certification information in feature titles
- Classification of localization features
- Country Codes - ISO 3166

Regulatory updates and communication

The following resources provide information about planned and new localization features.

Regulatory updates

- Regulatory updates
- Issue search in Lifecycle Services (LCS) (Updated daily)

Communication and alerts

- Regulatory watch and communication of regulatory updates
- Submit alerts about country/region-specific regulatory features

Dynamics 365 release plans

The Dynamics 365 release plans provide descriptions of new and enhanced capabilities that are planned for Dynamics 365 business applications and application platforms.

Finance and Operations apps what's new

The What’s new or changed in Finance and Operations home page lists the features that are included in specific releases of the Finance and Operations apps.
Electronic reporting

The Electronic reporting (ER) tool allows you to configure formats for electronic documents in accordance with the legal requirements of various countries/regions. ER lets you manage these formats during their lifecycle. For more information, refer to one of the following topics:

- Electronic reporting (ER) overview
- Manage the Electronic reporting (ER) configuration lifecycle
- Create Electronic reporting (ER) configurations
- Extend the list of Electronic reporting (ER) functions
- Electronic reporting (ER) destinations
- Download Electronic reporting configurations from Lifecycle Services
- Import Electronic reporting (ER) configurations
- Configure Electronic reporting (ER) to pull data into Power BI
- Generate electronic documents and update application data by using ER

Task guides

Task guides are available from the product help pane and they provide a guided walk-through of key business processes. You can open a task guide to read the steps of a business process or you can play a task guide to walk through a business process and enter data.

To find task guides, navigate to a page in the application and click Help. Task guides that use the page are listed in the help pane. You can also use the help pane to search for task guides by title.

To learn more, see Help system.

As part of the requirements for LCS solutions for localization and translation, localization features must be classified as either regulatory or competitive in the business process modeler (BPM) library in Microsoft Dynamics Lifecycle Services (LCS). This article explains the difference between these two types of feature and shows how the feature type is used in the title of the feature.

Localization features must be classified as either regulatory or competitive in the Business process modeler (BPM) library in Microsoft Dynamics Lifecycle Services (LCS). The following definitions will help you distinguish the two types of features:

- **Regulatory features** – Organizations that do business in a particular country/region must comply with country/region-specific laws and regulations as they handle their daily business transactions and operations, and meet their legal obligations for activities that are conducted in that country/region. These laws and regulations are enforced, and non-adherence can lead to severe consequences for an organization that does business in that country/region.

- **Competitive features** – This category includes all other features that aren’t considered regulatory features according to the preceding definition.

When the BPM library is constructed, the various feature types should be distinguished through the title of the localization solution feature. The label for this title will conform to the following naming convention that indicates the country/region and feature type through prefixes, as shown in the following table.

<table>
<thead>
<tr>
<th>FEATURE TYPE</th>
<th>FORMAT</th>
<th>EXAMPLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regulatory</td>
<td>XX-REG-Feature title</td>
<td>PT-REG-Direct sales tax report</td>
</tr>
<tr>
<td>Competitive</td>
<td>XX-COMP-Feature title</td>
<td>PT-COMP-Country bank payment format</td>
</tr>
</tbody>
</table>

The following table explains the components of the naming convention.

<table>
<thead>
<tr>
<th>COMPONENT NAME</th>
<th>FORMAT</th>
<th>DESCRIPTION</th>
<th>EXAMPLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Country/region code</td>
<td>XX</td>
<td>The two-letter ISO country/region code (from the ISO 3166 standard)</td>
<td>PT (= Portugal)</td>
</tr>
<tr>
<td>Feature type</td>
<td>REG or COMP</td>
<td>The type of feature</td>
<td>REG</td>
</tr>
<tr>
<td>Feature name</td>
<td>Text</td>
<td>A short feature title that describes what the feature is used for</td>
<td>Direct sales tax report</td>
</tr>
</tbody>
</table>

### Additional resources

- [Globalization resources](https://docs.microsoft.com/en-us/dynamics365/lifecycle-services/globalization-overview)
As part of the requirements for LCS solutions for localization and translation, localization ISV solution providers must implement all country-specific or region-specific functionality so that it can be controlled by country/region context. This article describes how to apply country/region context to meet these requirements. In this article you can find information how you should use country context property and what application objects control user interface elements.

### Country/region-specific functionality

You use country/region-specific functionality to help meet the legal, regulatory, and business requirements of individual geographies. A geography is any country or region that is identified by an International Organization for Standardization (ISO) country or region code. The following table highlights the main elements that you use to configure country/region-specific functionality.

<table>
<thead>
<tr>
<th>ELEMENT</th>
<th>DESCRIPTION</th>
</tr>
</thead>
</table>
| Controlled entity | The controlled entity is a UI element that is hidden or shown, depending on whether its country/region context matches the country/region context of the controlling entity. To enable menus, menu items, and form controls that are based on country/region context to be hidden, a controlled entity includes a `CountryRegionCodes` property on some elements. You use this property to specify the country or region where the element is shown. You find the `CountryRegionCodes` property on the following Application Object Tree (AOT) elements:  
  - Extended data type  
  - Menu and menu items  
  - Enum and enum value  
  - Table and table field  
  - Data entity and data entity field  
  - View and view field  
  - Map and map field  
  - Form control  
  - Tile |
| Controlling party | The controlling party's role is used to determine whether country/region-specific functionality or UI elements are enabled. The controlling party is defined by the Organization model. Examples include legal entity, customer, vendor, bank, or worker. By default, the legal entity is used as the controlling party. If the country/region context of the controlling party matches the country/region context of the controlled entity, the functionality or UI elements are enabled. You set the country/region context of the controlling party. Any controlled entities that have a matching country/region context are shown. |

### Using the CountryRegionCodes property

You create country/region context on a controlled entity by setting the ISO code value on the
**CountryRegionCodes** property. You can find the list of ISO country and region codes on the ISO website. The values of the **CountryRegionCodes** property are compared to the country/region context of the controlling party. If the values match, the element is shown. Otherwise, it's hidden.

**TIP**
To add more than one ISO country and region code to the **CountryRegionCodes** property, use a comma-separated list.

**Using the legal entity as the controlling party**

The **Country/region** value in the primary address of the legal entity determines the country/region context of the controlling party. The default value of the **Country/region** field is the locale of the system. The following illustration shows how to set the primary address of the legal entity.

![Primary address of the legal entity](image)

**Setting another party as the controlling party**

You can use another party, such as a customer, bank, or vendor, as a controlling party. For example, you can enable targeted functionality for customers of a specific country/region or require specific validation of vendors from a specific country/region. To set the controlling party, use the **CountryRegionContextField** property of the form, control, or other element. This property lets you select the entity that is the controlling party. The default value is the legal entity. The following illustration shows how to set the **CountryRegionContextField** property for a field.

![Setting another party as the controlling party](image)
In this example, the customer becomes the controlling entity. The customer’s address is compared with the value of the `CountryRegionCodes` field to determine whether the `GermanSpecificSetting` field is displayed.

**Additional resources**

ISO codes
As part of the requirements for LCS solutions for localization & translation, localization ISV solution providers must include details about any regulatory certifications that the solution requires in order to be legally compliant for sale in the intended market. This article shows how information about certifications is used in the title of the feature.

Regulatory certification can take various forms, from data privacy to certification of compliance with specific regulations. However, one thing that all regulatory certifications have in common is that they are required by the laws and regulations of the country/region of operation. These certifications are enforced, and non-adherence can lead to severe consequences for an organization that does business in that country/region. When the business process library is constructed, regulatory certifications must be identified as regulatory requirements in the Microsoft Dynamics Lifecycle Services (LCS) Business process modeler (BPM) library through the title of the localization solution feature. The label for this title will conform to the following naming convention that indicates the country/region and certification type through prefixes, as shown in the following table.

<table>
<thead>
<tr>
<th>FEATURE TYPE</th>
<th>FORMAT</th>
<th>EXAMPLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Regulatory</td>
<td>XX-REG-Certification for xx</td>
<td>PT-REG-Certification for Fiscal printers</td>
</tr>
</tbody>
</table>

The following table explains the components of the naming convention.

<table>
<thead>
<tr>
<th>COMPONENT NAME</th>
<th>FORMAT</th>
<th>DESCRIPTION</th>
<th>EXAMPLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Country/region code</td>
<td>XX</td>
<td>The two-letter ISO country/region code (from the ISO 3166 standard)</td>
<td>PT (= Portugal)</td>
</tr>
<tr>
<td>Feature type</td>
<td>REG</td>
<td>The type of feature</td>
<td>REG</td>
</tr>
<tr>
<td>Certification name</td>
<td>Text</td>
<td>A short title that describes the certification and its application</td>
<td>Certification for Fiscal printers</td>
</tr>
</tbody>
</table>

In the BPM business process library, certifications should be located under **APQC level 8.0 Manage Financial Resources (10009)**.

**Example**

- APQC level 8.0 Manage Financial Resources (10009)
  - PT-REG-Certification for Fiscal printers

For more information about BPM, see [Flowcharts in Business process modeler (BPM)](https://docs.microsoft.com/en-us/...).
As part of the requirements for LCS solutions for localization & translation, localization ISV solution providers must undertake their regulatory watch by taking advantage of localization tools in Microsoft Dynamics Lifecycle Services (LCS).

### Set up an alerting project in LCS

Localization independent software vendor (ISV) solution providers must create a new project in Microsoft Dynamics Lifecycle Services (LCS) to record regulatory alerts.

Follow these steps to set up the project.

1. Add a new project by clicking the plus sign (+).

2. Enter a name that uses the following project naming convention: **REG-Alerts-Country/region name**

3. Enter a project description.

4. For the product name, specify the latest version of your Dynamics 365 Finance and Operations app.

5. For the product version, specify the latest version.

6. Specify the industry:
   - Select **Other** if the solution is related to all industries.
   - Select an appropriate specific industry.

7. For the methodology, specify **Sure step**.

8. Click **Create**.

### Invite participants to the project

Invite participants that should have access to the project, so that they can submit and review regulatory alerts. For information about how to invite users, see Configure Lifecycle Services (LCS) security.

### Access the regulatory alert submission service

1. In your LCS project, scroll to the right side of the page, and then, under **More tools**, click Localization and translation.
2. Select Dynamics Regulatory Alert Submission, and then click Enter. The Dynamics Regulatory Alert Submission page opens. Use this page to view any previous alerts that have been submitted by you or your organization.

Submit a regulatory alert

To enter a new regulatory alert, click the plus sign (+) at the top of the form, above the filter. The Submit regulatory alert wizard starts. Follow these steps to complete the wizard.

1. On the Search for existing items page, follow these steps:
   a. Use Issue search to identify whether a regulatory feature that is related to the alert already exists. Enter search terms to specify criteria such as a keyword, country/region, Microsoft Knowledge Base (KB) number, or Application Object Tree (AOT) object. For example, you can search for the payment term “SEPA” to return related items.
   b. After you've finished entering the search terms, click the Search button. Search returns all items that meet search criteria as it searches across both product issues and regulatory features.
   c. You can narrow down the search results by using the filter/criteria that are available.
   d. If you don't find the regulatory feature that you're searching for, you can submit a regulatory alert by clicking Submit regulatory alert on the bottom ribbon.

2. On the Attach business processes page, follow these steps:
   a. In the Global business process libraries field, you can select business process libraries.
   b. You can enter search criteria to return business processes that are related to a search term. The tool highlights these business processes in yellow.
   c. You can drag business processes into the marked area on the left side of the page. You can select one or many related business processes in the process list. After you've dragged business processes to the marked area on the left, you can edit them further. Deselect business processes by clicking the x.
   d. When you've finished, click Continue to go to the next page in the wizard. When you receive a
If no relevant business processes are found, you can skip this page in the wizard.

You receive a message that asks whether you want to add the selected business processes to the alert. You can click either Yes or Cancel.

3. On the **Describe the alert** page, follow these steps:

   a. Enter information for the alert in the appropriate fields. Required fields are indicated by a red asterisk (*). The following table provides more information about the submission fields.

<table>
<thead>
<tr>
<th>FIELD NAME</th>
<th>FIELD TYPE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>Text</td>
<td>A descriptive title to identify the area of impact. For example, you might enter <em>Changes in invoice document per Jan. 1st 2014</em>.</td>
</tr>
<tr>
<td>Description</td>
<td>Text</td>
<td>A brief, pragmatic overview of the law. The description should focus on issues that are relevant to enterprise resource planning (ERP). It should have three to ten lines of details, so that users gain a high-level understanding of the requirement without having to read the legislation first.</td>
</tr>
<tr>
<td>Country</td>
<td>Valid values list</td>
<td>The country/region that the legislation applies to.</td>
</tr>
<tr>
<td>Industry</td>
<td>Valid values list</td>
<td>A list of industries, if the requirement applies only to selected industries (for example, Public sector, Retail, or Communication).</td>
</tr>
<tr>
<td>Link to legislation</td>
<td>Text (URL format)</td>
<td>Add links to the published law, interpretation guideline, implementation guidance, or any other documentation that will be useful for understanding and implementing the requirement.</td>
</tr>
<tr>
<td>Feature reference</td>
<td>Text</td>
<td>The feature reference ID (if it's known).</td>
</tr>
<tr>
<td>Law enforcement date</td>
<td>Date</td>
<td>Date from which impacted customers must comply with the law</td>
</tr>
<tr>
<td>Government announcement date</td>
<td>Date</td>
<td>The date when the authority announced the change.</td>
</tr>
<tr>
<td>FIELD NAME</td>
<td>FIELD TYPE</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>

You can upload up to three files, each of which can be up 5 MB. To delete a file that you've uploaded by mistake, click Remove under the file title. <strong>Important</strong>: Attachments must be publicly available materials. They can't be propriety or customer/partner specific.</td>
</tr>
<tr>
<td>Consent check box</td>
<td>Check box</td>
<td>Give appropriate consent to being contacted. The Submit button doesn't become available until you select this check box.</td>
</tr>
</tbody>
</table>

b. When you've finished adding all the required fields, you must provide appropriate consent by selecting the consent check box: By creating this alert I allow Microsoft to contact me in the future for any further information related to this alert. Read the Microsoft Dynamics Lifecycle Services privacy statement for more information.

c. After you select the check box, the Submit button becomes available. Click Submit to submit the alert. If you've partially completed an alert, you can save the information that you've already entered for later completion or review. Click Save before you submit the alert.
d. When you receive a confirmation message that states that the alert has been successfully submitted, click **Done** to exit the wizard. If you chose to save the alert before you submitted it, an alert ID is generated, and you are notified that the alert has been saved.

Review regulatory alerts that have been entered into the project

To view the regulatory alerts that have been entered into your alerting project, use the alert grid. This grid provides a high-level list view of the alerts that have been submitted, and shows the alert title, country/region, law enforced date, and so on.

You can search the contents of the grid by using the filter/search field and then selecting from the default search options. You can drill into the detail of an alert by clicking the alert ID, which is a hyperlink. The completed alert submission page opens, where you can review the alert details, and also any comments and attachments.

Process submitted alerts options

After an alert has been submitted to the LCS alert project, you can process it from the grid view by clicking the alert ID hyperlink. Project owners can then change the status of the alert to notify project members whether action will continue to be taken for the alert. Options appear when you drill into details of the alert.
The following table describes the processing options that are available for alerts.

<table>
<thead>
<tr>
<th>STATUS</th>
<th>STATE</th>
<th>ACTIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Submitted</td>
<td>The alert has been submitted to (entered into) LCS by a Loc. Community member.</td>
<td>The alert can be either received or rejected.</td>
</tr>
<tr>
<td>Received</td>
<td>The alert has been reviewed by an internal Sol. Partner resource and has been received for further review.</td>
<td>The alert is marked <strong>Received</strong>. A comment and feature reference can be added.</td>
</tr>
<tr>
<td>Rejected</td>
<td>The alert has been reviewed by an internal Sol. Partner resource and has been rejected.</td>
<td>The alert is marked <strong>Rejected</strong>. A comment must be added to explain why the alert was rejected.</td>
</tr>
<tr>
<td>Reopened</td>
<td>The alert was rejected but has been reopened by a Loc. Community member, and new/additional information has been entered (a comment is mandatory).</td>
<td>The alert can be reviewed again to assess whether it should be received or rejected.</td>
</tr>
</tbody>
</table>

**NOTE**

Submitted alerts can be rejected for various reasons. Here are some examples:

- The alert is too vague to identify the underlying localization feature.
- The alert is related to an area where no features are localized.
- The alert is related to an area that isn't currently supported by Finance and Operations functionality.

Alerts can be stored in LCS as references.

Further processing, such as potential engineering of a related feature, will be handled in the ISV solution provider’s existing systems.
As part of the requirements for LCS solutions for localization and translation, if a localization solution for previous versions of Dynamics 365 Finance and Operations apps contains both regulatory and competitive features, localization ISV solution providers must split the solution into separate models for each feature type. This article provides information about this requirement.

Multinational customers must comply with regulatory requirements in all countries/regions where they deploy Finance and Operations apps. At the same time, these customers want to minimize the cost of code maintenance. Therefore, if a localization solution for previous versions contains both regulatory and competitive features, the solution must be split into separate models, so that customers can adopt and deploy the features that they require. An effort has been made to split the Application foundation and Application suite stack into multiple models.

The number of models is expected to grow over time. Splitting a monolithic code base provides many benefits, such as better scalability, manageability, and serviceability. The localization requirement to split a localization solution into more granular models builds on this effort. The goal is to provide the same benefits to multinational customers.

After you’ve classified features as either regulatory or competitive, as described in Classification of localization features, split the code for these features into at least two models, one model for the regulatory features and at least one model for the competitive features. If the competitive features can be split further (for example, into features that are related to Commerce and features that are related to Fixed assets), it's a good idea to split them. However, further splitting isn't mandatory. For more information about how to split the stack into multiple models, see Model split.
This topic describes how to use Microsoft Dynamics Lifecycle Services (LCS) to submit alerts through the Dynamics regulatory alert submission service. This topic also explains how to track planned and released regulatory features through LCS Issue search.

Accessing the regulatory alert submission service

In Dynamics Lifecycle Services (LCS), in your project, scroll to the right side of the page, and then, under More tools, click the Alert service tile.

The Dynamics regulatory alert submission page appears. You can use this page to view any alerts that have previously been submitted by you or your organization.

Submitting a regulatory alert

To enter a new regulatory alert, click the plus sign (+) at the top of the Dynamics regulatory alert submission page, above the filter. The Alert submission wizard starts. You can complete the following tasks in this wizard:

- Search for existing regulatory items.
- Attach business processes.
- Describe an alert.
- Confirm submissions.

Search for existing regulatory items

Use Issue search to identify whether a regulatory feature, that is related to the alert, already exists.

1. Enter a search term, such as a keyword, country/region, Microsoft Knowledge Base (KB) number, or Application Object Tree (AOT) object. Click the search button. Any items that include the search term, in either product issues or regulatory features, appear in the search results. You can narrow the search by using the filters that are available.

2. If you don’t find the regulatory feature that you’re looking for, you can submit a regulatory alert by clicking Submit regulatory alert at the bottom of the browser window.

Attach business processes

1. In the Global business process libraries list, select business process libraries.

2. Enter search criteria to find business processes that are related to the search term. These business processes are highlighted in yellow.

3. In the list on the right side of the page, select one or more related business processes, and drag them into the field on the left. After you’ve finished, you can edit them further by clearing the selection of business processes.

4. Add the selected business processes to the alert.

Describe the alert

1. Enter information about the alert in the appropriate fields. Required fields are indicated by a red asterisk.

The following table provides more information about the fields on the Describe the alert page.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>Enter a descriptive title to identify the area of impact. For example, enter <em>Changes in invoice document as of January 1, 2018</em>.</td>
</tr>
<tr>
<td>Description</td>
<td>Enter a brief overview of the law. Your description should focus on issues that are relevant to enterprise resource planning (ERP), so that users can understand the requirements at a high level without having to read the legislation first.</td>
</tr>
<tr>
<td>Country</td>
<td>Select the country or region that the legislation applies to.</td>
</tr>
<tr>
<td>Industry</td>
<td>Select the industry, if the requirement applies only to specific industries. For example, select <em>Public sector, Commerce, or Manufacturing</em>.</td>
</tr>
<tr>
<td>Feature reference</td>
<td>Enter the feature reference, if you know it.</td>
</tr>
<tr>
<td>Law enforcement date</td>
<td>Select the date when affected customers must start to comply with the law.</td>
</tr>
<tr>
<td>Government announcement date</td>
<td>Select the date when the authority announced the change.</td>
</tr>
<tr>
<td>Latest filing date</td>
<td>Select the deadline for the first submission of the new or changed report.</td>
</tr>
<tr>
<td>Link to legislation</td>
<td>Enter one or more links to the published law, interpretation guideline, implementation guidance, or any other useful documentation that will help users understand or implement the requirement.</td>
</tr>
<tr>
<td>Company name</td>
<td>Enter the company name for the person who is submitting the alert.</td>
</tr>
<tr>
<td>Contact name</td>
<td>Enter the name of the person who is submitting the alert.</td>
</tr>
<tr>
<td>Contact email</td>
<td>The email address of the person who is submitting the alert.</td>
</tr>
</tbody>
</table>
2. After you’ve finished entering all the information, select the consent check box (By submitting this regulatory alert, I consent to Microsoft contacting me for additional information about this alert. Microsoft Privacy Statement.). When you select the check box, the Submit button becomes available.

3. Click Submit to save and submit the alert.

If you don’t have all of the required information, or if you’re not yet ready to submit the alert, you can save a partially completed alert.

Confirm your submission
- When the alert is successfully submitted, you receive a confirmation message. Click Done to exit the wizard.
- If you save the alert before you submit it, an alert ID is generated, and you receive confirmation that the alert has been saved.

Track the status of regulatory features in Issue search
You can use Issue search in LCS to find planned and released regulatory features, and any associated localization documentation, certifications, and reports. To narrow your search to regulatory features, use the following filters:

- **Category** - Select Regulatory feature only.
- **Country/region** - Click > to select the country/region that you’re interested in.

To narrow the search even more, you can apply the following additional filters

- **Product** - Select the products and product versions that you’re interested in.
- **Status** - Select specific statuses.
This topic explains how to get help with Finance and Operations apps or Microsoft Dynamics Lifecycle Services (LCS).

<table>
<thead>
<tr>
<th>TASK</th>
<th>MORE INFORMATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ask the community.</td>
<td>Go to the Dynamics 365 Community page to get help with your questions from the Microsoft Dynamics community.</td>
</tr>
<tr>
<td>Get help with questions about licensing.</td>
<td>Contact your partner or a Microsoft sales representative.</td>
</tr>
<tr>
<td>Use the <strong>Issue search</strong> tool.</td>
<td>In LCS, use the <strong>Issue search</strong> tool to quickly search for Microsoft Knowledge Base (KB) articles, hotfixes, and workarounds for reported issues. You can see which reported issues are in the process of being fixed for a specific functional area, and which issues have already been fixed. For more information, see <strong>Issue search (Lifecycle Services, LCS)</strong>.</td>
</tr>
<tr>
<td>Get support within your Finance and Operations app.</td>
<td>Select the <strong>Help</strong> button (?) in the upper-right corner of the app, and then select <strong>Support</strong>. Issues are reported on the <strong>Active issues</strong> tab in LCS. There, admins can determine whether they should provide in-house support or submit the issues to Microsoft.</td>
</tr>
</tbody>
</table>
| Open a support ticket with the Microsoft Support team. | In LCS, the **Support** tile opens a tool that helps you manage support incidents. To submit issues directly to Microsoft, select the **Support** tile in your LCS project. You can then submit issues in two ways:  
  - On the **Active issue** tab, select your issue, and then select **Submit to Microsoft**.  
  - On the **Submitted to Microsoft** tab, select **Submit an incident**, and then follow the on-screen instructions to submit the incident. After you submit an incident, you will receive an email message from the Microsoft Support engineer who is assigned to your case. |
| Request new features and functionality.          | Visit Dynamics 365 Application Ideas to view, search, or vote for existing ideas, or to add new ideas. |
Finance and Operations apps provides many self-service support options and support through 21Vianet.

**Self-help resources**

- Finance and Operations application documentation
- Help resources for Supply Chain Management
- Finance and Operations apps - operated by 21Vianet in China
- Dynamics community
- Microsoft Learn

**Assisted support**

- Open a support request

**Presales support**

Pre-sales support phone number: +86 400-886-6134

Pre-sales support provides assistance on subscription features and benefits, plan comparisons, pricing and licensing, and helps to identify the right solution to meet your business needs. In addition, pre-sales support can help you find a Partner, and purchase and sign up for a trial. You can call during local business hours, Monday through Friday.

**Billing and subscription management support through 21Vianet**

Billing and subscription support telephone number: +86 400-089-0365.

Assistance for billing and subscription management issues is available online or by telephone Monday through Friday during local business hours 9:00 to 18:00 China Standard Time (CST). Billing and subscription management support can be accessed using the same phone number and online service request process as with technical support.

Here are some examples of billing and subscription management issues:

- Signing up for a trial or purchasing a subscription.
- Converting from a trial subscription to a paid subscription.
- Understanding the bill.
- Renewing a subscription.
- Adding or removing licenses.
- Canceling a paid subscription.

**Assisted Technical support through 21Vianet**

When you experience a technical issue with your deployment, report it to 21Vianet through the LCS portal or by calling the support number at +86 400-089-0365. Technical support hours of operations are Monday through Friday during local business hours 9:00 to 18:00 China Standard Time (CST).

A support request (SR) is handled within hours, depending on the severity of its impact to your business.
• **Critical business impact** - You will receive an initial response within 1 hour or less, and a support representative will work continuously, all day, until the problem is resolved. You will be expected to allocate appropriate resources to work on the request until the problem is resolved and provide accurate contact information to the support personnel handling your case.

• **Non-critical business impact** - You will receive an initial response within 8 hours or less. You will be expected to provide accurate contact information to the support personnel handling your case.

**Get Premier support**

If you run mission-critical solutions, Premier support offers additional value:

- Proven advisory services designed to maximize your Dynamics 365 investment.
- A designated service delivery manager committed to improving your Dynamics 365 experience.
- Top priority reactive support to help ensure service continuity.

For details about purchasing Premier support, contact your Microsoft Account team. If you have a Premier support plan you can contact support via My Premier Online.

**Additional resources**

- Dynamics 365 support site for 21Vianet (Chinese)
- Finance and Operations apps - operated by 21Vianet in China
- Model-driven apps in Dynamics 365 - operated by 21Vianet in China
- Dynamics 365 Privacy statement (Dynamics 365 隐私声明)
- Dynamics 365 Service Level agreement (世纪互联在线服务的服务级别协议)

- Service terms for Dynamics 365 Lifecycle Services
- OSPT of Dynamics 365 (世纪互联在线服务的服务级别协议)
- Azure Docs (in Chinese)
- Azure China 21Vianet
Prerequisites

Before you can set up technical support, you must acquire a Microsoft Azure Active Directory (Azure AD) account. This account is created when you set up a subscription for one of the Microsoft Dynamics 365 Finance and Operations apps.

Create an Azure DevOps project

The Support tile in a Lifecycle Services (LCS) project uses Azure DevOps to store issues that are submitted through the client and issues that are manually created from the Support tile in LCS. This functionality requires that an Azure DevOps project be configured in the LCS project that you want to use for support. All users who need to use the Support tile to submit an issue must have access to the Azure DevOps project, and must authorize LCS to access Azure DevOps on their own behalf. Most users don't have access to LCS or Azure DevOps. Therefore, in the Azure DevOps project, you should create a special system account that can be used to submit issues.

Create a new Azure DevOps project

2. Click Sign in in the upper-right corner.
3. Sign in by using an AAD account that is in the tenant that your subscription is linked to. If the browser already has your credentials, you won't see the sign-in page and should instead click your name in the upper-right corner.
4. On the right side of the page, under Accounts, click Create a free account now.
5. Specify an account URL, and then click Create Account.
6. Name your project, and specify a process template. Your project should now be created.

Add users to the Azure DevOps project

1. In the upper-left corner, click Team Services.
2. On the Users tab, click Add, and invite users who will use the Support experience to the Azure DevOps account. For each user that you invite, select either Basic or Stakeholder.
3. In the upper-left corner, click Team Services.
4. Click Browse, and browse to the project that you created in the previous procedure.
5. In the Members section of the project home page, click Add, and add the users that you invited in step 2.

Create the Support system user

1. Create a new user in your Azure AD tenant, and enter a descriptive name, such as LcsCpsSystemAccount.
2. In the upper-left corner, click Team Services.
3. On the Users tab, click Add, and invite the system user that you created in step 1. For this user, select Stakeholder.
4. In the upper-left corner, click Team Services again.
5. Click Browse, and browse to the project that you created earlier.
6. In the Members section of the project home page, click Add, and add the system user.
Retrieve the personal access token for the Support system user

1. Sign out of Team Services by clicking the user name in the upper-right corner and then clicking Sign out.
2. Sign in to Team Services by using the Support system account that you created in the previous procedure.
3. In the upper-right corner, click the user name, and then click My profile.
4. On the Security tab, on the Personal access tokens tab, click Add.
5. Enter a description, such as LCS Support system account.
6. Select an expiration date of one year.
7. Click Selected scopes, and then select Work items (read and write).
8. Click Create token.
9. Copy the token and paste it in a safe location because it won't be accessible after you move away from the page.

Configure LCS

1. Sign in to LCS by using an account that has the Owner role for the LCS project that the application is deployed in.
2. Open the project in LCS.
3. Click Project settings, and then click the Azure DevOps link.
4. Click Setup Azure DevOps.
5. In the Azure DevOps site URL field, enter the URL of the Azure DevOps project that you created in the previous section.
6. In the Personal access token field, enter the personal access token that you created in the previous section.
Create an issue

The Support experience has been updated to show updates that are published by Microsoft. In the client, on the top bar, click ?, and then click Support.

WARNING

If you have an on-premises deployment, the option to search for existing issues and submit a support incident from the on-premises client to your Azure DevOps project is not available.
NOTE
If you haven't already connected to Lifecycle Services (LCS), a dialog box will display where you can connect. Click the link to connect before proceeding.

**Connect to Lifecycle Services**

Authorization must be given to Dynamics 365 for Operations in order to access Lifecycle Services. Click the link below to begin the authorization process. Once authorization has been granted return to this page and click the Ok button.

*Click here to connect to Lifecycle Services*

Search for a fix

After you connect to LCS, you can search for existing Microsoft published updates and fixes. Enter your issue in the **Search** box and press **Enter**.

NOTE
If you don't want the functionality to search for existing fixes enabled for all users, you can remove the **SearchExistingFixes** duty from the System user role and add it to only those roles which you want to have this functionality. Search results are based on the Microsoft Issue Search data that is relevant to your environment. Fixes that you have already installed will not be included in your search results. To view a specific result, click the link to view the details.

Based on the duties assigned to you, you will see either the **Download view** or the **Request view**.

- **Download view** - By default, this view is only available to system administrators. From this view, you can directly download the hotfix.

  NOTE
  The duty **DownloadHotfix** controls the ability to directly download fixes from LCS rather than requesting them. Only system administrators will have access to it by default. If you want to assign this duty to users other than system administrators, you can do so by adding the duty to the selected roles.

- **Request view** - By default, this view is available to all users who are not system administrators. From this view, you can make a request to download the hotfix. After you submit your request to download the hotfix, a work item will be created in the Azure DevOps project that is associated to your LCS project. The customer IT admin can view all requested hotfixes by clicking the **Support** tile in LCS and then clicking the **Hotfix requests** tab.

**Search for project work items in Azure DevOps**

The Azure DevOps administrator can publish project work items to your organization users by tagging the work items with **#SearchableInFinanceAndOperations**. The tagged work items will be searchable for users from the client support search box. The search result will include tagged Azure DevOps work items in addition to Microsoft published updates and fixes. The following graphic shows a tagged Azure DevOps work item for publishing.
When you search for published Azure DevOps work items using the support search box, search results show the work item’s type, title, state, and description in a new browser tab with view mode. Users with proper permissions can edit the work item in Azure DevOps. The following graphic shows the search result of a published Azure DevOps work item.

The published Azure DevOps work items are only visible to your organization's users.

Create and submit a new issue
If you don’t see a fix in the search results, you can create a new issue by clicking Create. This is the same functionality that is available for previous releases and is documented in earlier procedures.

Work with issues in LCS

View issues
In the LCS Support tile, issues are stored as work items in the Azure DevOps project that is associated with the LCS project. Specifically, issues are stored as work items of the Issue or Impediment type, depending on the type of Azure DevOps project, in the AxAndLcsGeneratedIssues area. Every work item of one of those types in that area will be included in the list of issues in the Support tile. If an issue is modified in Azure DevOps, the changes will be reflected in Support issues. Issues can be assigned to any user in the Azure DevOps project. Users don't need to have access to LCS to work with issues in Azure DevOps.

1. Go to lcs.dynamics.com, and sign in.
2. Open the LCS project that is associated with the environment that you want to view issues for.

3. Click the Support tile. A list of the issues that have been created appears.

### Edit issues

1. In the Issues grid, click the title of an issue.

2. If necessary, sign in to Azure DevOps by using an account that has access to the Azure DevOps project that you set up in the first section of this topic, Create an Azure DevOps project.

   **NOTE**
   
   There is an issue in Azure DevOps, where the link to edit work items doesn’t work correctly if sign-in is required. If you see the Assigned to me query after you sign in to Azure DevOps, go back to LCS, and click the title of the issue in the issue grid again.

3. The Azure DevOps editor opens. Edit the issue, and then save your changes. The changes will be reflected in the Support tile.

### Submit an issue to Microsoft

You can submit issues to Microsoft support. When you submit an issue to Microsoft, the information and attachments in the issue can be included in the Microsoft support incident.

LCS users must have a valid Microsoft support plan to submit issues to Microsoft. If you have trouble submitting issues to Microsoft, work with your administrator to make sure that your LCS credentials are added to or associated with your organization’s support plan with Microsoft Partner Source Business Center.

1. In the Issue grid, select the issue to submit to Microsoft, and then click Submit to Microsoft.

2. If your account is associated with multiple support organizations, select the organization to use to create the Microsoft support incident.

3. Use Issue search to verify that your issue hasn’t already been solved.

4. If Issue search doesn’t provide a solution to your issue, click Create incident at the bottom of the page.

5. Share diagnostic data with the Microsoft support team. By providing version information, your issues can be resolved more quickly.

6. Describe your issue, provide your contact information, and then click Submit.

### Support settings

**NOTE**

The information in this section is not applicable to on-premises deployments.

When you deploy your application from Lifecycle Services, no configuration is required, because the Support tool automatically saves any issues to the same LCS project that Finance and Operations was deployed from. To verify the LCS project that Support uses, go to System administration > Setup > System parameters, and
then click Help > Support Contact.

Prevent users from creating issues from the client

By default, the System user role has the privilege, SysLCSCPSIssueEntry assigned. This privilege controls access to the Contact your support team menu item on the Help menu. If you want to prevent users from being able to create and submit issues from the client, remove this privilege from the System user role.
Open a new incident

1. In LCS, go to the project for which you want to file a support incident.

2. Click the Support tile.

3. On the Submitted to Microsoft tab, click the Submit an incident button.

4. Select an issue category.

5. Select an issue area.

6. In the Describe your issue area, enter the following:
   - Select Yes if the issue occurred in an environment. Select the environment name.
   - Enter a short description of your issue in the Title field.
   - Provide details about the issue detail and the steps needed to reproduce the error.
   - If applicable, enter an error message.
   - If possible, attach screenshots that illustrate the problem. To do this, click Attach file from
7. Enter the primary contact information. These contact details will be used by the customer support team to contact you about the case.

8. Select the support contract and the severity level.

- Support contracts for on-premises environments have a limited incident count.
- Support contracts for cloud environments have an unlimited incident count.
- For on-premises products or cloud environments, from the list of available support contracts, select the support option to use if you have multiple tier support contracts.

9. Click **Submit**.

After you click **Submit**, an incident is created and added to the **Incidents** list. You will receive an email message from the Microsoft Support Engineer assigned to your case.

**Support plans in Lifecycle Services**

Support plan entitlements are derived based on several different identifiers. Not all will apply to your situation. If you are missing a support plan or entitlement in LCS, determine which identifier is needed to tie it to your project in LCS. If there is more than one organization, note which one is current by clicking on your name in the upper-right corner of LCS. Select the organization that applies to your scenario and contains the benefits that you want to utilize.

**Unique contract ID/access ID**

The following online support plans require a unique contract ID/access ID combination linked to your sign-in in LCS:

- Unified
- Premier
- Advanced support for partners

If you do not know your unique contract ID/access ID combination, contact your Microsoft account manager to have an ID created for you.

To link your contract ID/access ID to your account, complete the following steps:

1. From within a project, select **Support** from the main menu, and then select **Manage Support plans**.

2. Select **Add contract**.

3. Enter your access ID and your password or contract ID, and then select **Add contract**.
**PartnerSource Business Center account**

The following support plan incidents can be used as part of your PartnerSource Business Center (PSBC) account if they exist:

- Advanced support for partners on-premises incidents.
- Advantage or Advantage + on-premises incidents.
- Other pay per incident types of plans with an existing incident count in PSBC.

If you do not find the PartnerSource Business Center account, ensure that your sign in is added as a professional in your organization in PSBC. Make sure that you are signing in with the same Microsoft or work account login. This account is only applicable in an on-premises project.

**Sign-in specific options**

The following incidents and support benefits will appear based on your sign in, if applicable:

- MPN gold and silver incidents.
- Signature cloud support.
- Individual incidents and 5 packs purchased on [support.microsoft.com/supportforbusiness].

**NOTE**

Incidents must be purchased with a Microsoft account such as @hotmail.com or @outlook.com. Work or Azure Active Directory accounts cannot have incidents tied to them.

**Tenant subscription**

The following entitlements will appear based on your subscription and ProDirect purchases within your tenant organization:

- Subscription
- ProDirect

**Software assurance**

The following entitlements can be added by linking a subscription number and contact email:

- Software assurance
To add, select **Add a Software Assurance plan** when you create the support incident. Enter the subscription number and the contact email, and then click **Continue**.

Report production outage

For a quick and effective way to escalate issues to Microsoft Support in the event that the services in a production environment are degraded or become unavailable, see **Report a production outage**.

Phone support

We prefer that you contact Support following the steps in **Open a new incident**. If you’re unable to open a new incident in LCS, phone support is available using **Premier phone support**.
To ensure a good experience during the implementation of a project and after go-live, it's important that you understand the different types of servicing that are available and how you can get the correct support for every scenario. This topic explains how to engage each type of support and learn about some of the tools available.

Microsoft tools and support help ensure the stability and effectiveness of your environment by providing infrastructure and application support. However, this support can be effective only if partners and clients correctly develop, test, configure, manage, and monitor the implemented system and its environments.

Supporting actions can be grouped into three categories:

- **Self-service**
- **Service request**
- **Support request**

Depending on the category, the actions are triggered in different ways and might involve different lead times.

**Self-service**

Self-service actions can be triggered by users at any time and involve no lead time. Here are some of the reasons why a user might initiate a self-service action:

- Promote code (in non-production environments).
- Move databases between non-production environments.
- Upgrade a production environment.
- Turn maintenance mode on or off
- Pause upcoming automatic deployment of a service update.
- Restart services in non-production environments.
- Complete performance actions.

**Service request**

Service requests are usually triggered by creating a support ticket. They involve the cooperation of the Dynamics Service Engineering (DSE) team. Each request will involve designated lead time. A service request might be created to request environment deployment, for example.
Recommended practices for working with the DSE team

- Consider that there are turnaround times or Service Level Agreements (SLAs) for each type of service request.
- Don’t use a service request if a support request is more suitable for your case.
- To ensure that you make the correct type of request, see Service request types and SLAs.

Support request

Other scenarios can usually be resolved by opening a support request. These requests involve lead time. Here are some of the reasons for creating a support request:

- Do a point-in-time restore of a production environment after go-live.
- Flag a regression in a service update, and ask for an exception opt-out.
- Make performance-related requests (for tasks that can’t be completed through self-service).
- Activate a flying feature (for example, customer and vendor master data sharing).
- Resize a production environment. (You must first update and upload a new usage profile in the subscription estimator in Microsoft Dynamics Lifecycle Services [LCS].)
- Create an additional LCS project in the same tenant.
- Move the tenant of production environments.

Requesting support

An effective support process requires that a clear escalation path be defined. Project teams (client or partner) should be able to monitor and read environment telemetry, and they should be capable of doing any initial troubleshooting that is required.

A well-identified issue and a well-defined resolution process can make a difference in the effectiveness of the outcome.

An effective support request should include the following details:

- The environment where the issue occurs
- The process that the issue was identified in
- Reproducible steps to show where the issue occurred
- The expected result and the actual result
- Pre-investigation of the issue
- Additional elements (for example, the error message, screenshots, the session ID, and the trace)

High-severity support requests

A high-severity support request should include the following information:

- **Business impact:** How does the issue affect your business activities?
- **Financial impact:** How does the issue affect your business at a financial level?

A thorough analysis of each issue should be done before the issue is reported. The incident resolution will be much quicker if the support request includes detailed information, and if all available tools and telemetries have been used. By including all the correct information when you submit a support request, you reduce the amount of back-and-forth communication that is required to identify and replicate the issue. Therefore, you can save lots of time.

There are several support plans to choose from. Therefore, every business should be able to find a plan that meets its needs.

Before you request support, it’s important that you choose the correct level of severity. For information about how to identify the correct severity level and estimate the initial response time for your request, see Support.
LCS has an integrated set of tools that you can use to monitor LCS projects.

**Service health dashboard**

The Service health dashboard provides the health status for Office 365 services.

You can also view the service health through the Microsoft 365 admin center. Go to Health > Service health, or select the Service health card on the Home dashboard.

By default, the All services tab is selected on the Service health page. It shows all services and their current health state. A symbol and a value in the Status column indicate the state of each service.

If you're experiencing an issue with a Microsoft 365 service, but it isn't listed on the Service health page, you can notify Microsoft by selecting Report an issue and completing a short form.

The issue reporting will help to identify issues and how widespread they are. After incidents are identified, they will be shown on the dashboard under service health.

You can sign up to receive email communication. In this way, you can ensure that you're quickly alerted about issues that are identified in the tenant and their status change.

**Environment monitoring**

Environment monitoring is a set of tools that help you monitor and troubleshoot the health of your environments through LCS.

On a specific environment page for a project, the Monitoring section includes a Environment monitoring link that will take you to the Environment monitoring dashboard.

The following subsections describe some of the tools that are available.

**Overview**

The Overview section is common to most environment types. It provides a filterable way to trace user activity and to trace load by activity during a defined period.

**Activity**

The Activity tab lets you query raw logs. It provides predefined queries for the most common events and metrics to help you monitor your environment. Here are some examples of the predefined queries that are available:

- Slow queries
- Deadlocks
- Crashes
- Financial reporting issues
- Batch throttle
- Distinct user sessions

Additionally, you can add your own custom filters and export the logs to a comma-separated values (CSV) file for analysis.
Health Metrics

The **Health Metrics** dashboard provides a series of line charts that are filtered by instance (AOS or Batch AOS) and time frame. On the **AOS** tab, you can observe SQL execution. On the **System** tab, you can observe system memory and CPU utilization over time. This tool lets you easily identify behavioral changes. Therefore, it can help you trace issues over time and the impact of changes in the solution.

For additional content related to monitoring LCS environments, see [*Performance troubleshooting using tools in Lifecycle Services (LCS)*](#).

Although it’s important that you monitor your environments, you don’t have to be on constant lookout. Microsoft also uses the emails that are provided in the LCS notification list to alert you about important issues and actions that you must take, and to provide preventive guidance for the implementation itself.
This topic points to content for system administrators of Finance and Operations. This content will help you configure the system so that it works smoothly and effectively for your organization.

One Version

In July 2018 we announced a change to the way we deliver Dynamics 365 updates that will help you stay current in a consistent, predictable, and seamless manner. The following topics are intended to provide clarity on the Finance and Operations service updates, processes, and tools you can use to stay current.

- One Version service updates overview
- One Version service updates FAQ
- Service update availability
- Apply updates to cloud environments
- Configure service updates through Lifecycle Services (LCS)
- Pause service updates through Lifecycle Services (LCS)
- Get notified about service updates through Lifecycle Services (LCS)

Implementation management with Lifecycle Services

Microsoft Dynamics Lifecycle Services (LCS) is a collaboration portal that provides an environment and a set of regularly updated services that can help you manage the lifecycle of your Finance and Operations implementations.

The lifecycle of an implementation spans many phases from pre-sales through Analysis, Design and Development, Test, and Deployment to Operation, possibly in multiple iterative roll-outs. It can last a few months to multiple years, based on the scope and complexity of the project and the chosen deployment model, for example, in the managed cloud or on-premises.

The management of the implementation involves many different stakeholders from the customer and partner organizations and, especially in the cloud-hosted deployment model, from Microsoft. The implementation is supported through tools provided on LCS and through processes defined within the Microsoft FastTrack and through the partner’s implementation approach.

- Lifecycle Services resources
- Lifecycle Services (LCS) user guide

Deployment

You can deploy in the cloud or on-premises. Cloud deployments offer an enterprise resource planning (ERP) service that is fully managed by Microsoft. On-premises deployments are deployed locally in a customer’s data center.

- Software lifecycle policy and cloud releases
- Cloud deployment overview
- System requirements for cloud deployments
- On-premises deployment home page
- System requirements for on-premises deployments
Upgrade

An upgrade can involve moving to a new product version, migrating and upgrading code, moving to an update, or deploying a hotfix.

Although the processes for each type of upgrade are similar, they differ enough that you should review the topics for a specific task before you begin.

- Upgrades, updates, and hotfixes resources

Database management

For information to help you move a database to new environment and restore a database to a specific point in time, see Database movement operations home page.

Security

Finance and Operation apps uses role-based security. Access is granted only to security roles, not to individual users. Users are assigned to roles. A user who is assigned to a security role has access to the set of privileges that is associated with that role. A user who isn't assigned to any role has no privileges.

Role-based security is aligned with the structure of the business. The security roles that a user is assigned to depend on the user's responsibilities in the organization, and their participation in business processes. The administrator grants access to the duties that users in a role perform, not to the program elements that users must use.

Because rules can be set up for automatic role assignment, the administrator doesn't have to be involved every time that a user's responsibilities change. After security roles and rules have been set up, business managers can control day-to-day user access, based on business data.

- Role-based security
- Security architecture
- Encryption in Finance and Operations apps

Batch processing

Many tasks can be run as part of batch jobs. For example, batch jobs can include tasks for printing reports, doing maintenance, or sending electronic documents. By using batch jobs, you can avoid slowing down your computer or the server during typical working hours.

- Batch processing overview
- Batch processing and batch servers

Optimization advisor

- Optimization advisor overview
- Optimization advisor (video)
- Create rules for Optimization advisor

Office integration

The integration with Microsoft Office provides a set of productive, collaborative, and integrated user experiences that take advantage of the Microsoft Office suite. This functionality can help your organization become more efficient and effective.

- Office integration overview
Mobile

The Finance and Operations mobile app enables your organization to make its business processes available on mobile devices. After you enable the mobile workspaces for your organization, users can sign in to the app and immediately begin to run business processes from their mobile devices.

- Mobile app home page
- Available mobile workspaces

Process Automation

The process automation framework allows administrators to view and create automated processes that will be scheduled with the batch server. The added layer of visibility of scheduled work is presented in a calendar view that can be extended for use in application areas to allow non-system administrator users to view work that impacts their area.

- Process Automation home page

General administration

- Demo data overview
- Cross-company data sharing
- Add links to your organization’s legal terms and privacy statement
- License codes and configuration keys report
- Maintenance mode
- Preconfigured system accounts
- Export business-to-business (B2B) users to Azure Active Directory
- Set the session inactivity timeout
- Build OData metadata cache when AOS starts
- Configure and manage database logging
This topic explains how administrators can add links to their organization's legal terms and privacy statement in the About pane of Microsoft Dynamics 365 Finance, Supply Chain Management, and Commerce.

Organizations often need to ensure that the links to their legal terms and privacy statement are readily available and visible to users in order to meet legal and compliance requirements. Administrators of an organization can follow these steps to have the links to their legal terms and privacy statement be available in the About pane (Settings > About).

Add links

1. Go to the System parameters page and click Legal and Privacy. On this page:
   a. Enter the link to a page that outlines the legal terms for your organization.
   b. Enter the link to a page that outlines the privacy statement for your organization.

   **NOTE**
   Make sure that you enter the full URL, starting with either https or http.

2. Click Save.

3. If you are using Commerce, go to the Distribution schedules page. On this page:
   a. Select the 1110 – Global configuration job.
   b. Click Run now.

   **NOTE**
   To verify that the job completed, go to the Download sessions page.

Validate links

**Validate the links in Finance, Supply Chain Management, and Commerce**

To validate that the links have been added, on the toolbar at the top of the page, click the Settings icon, and then click About. In the Links section of the pane, you should see two new links:

- Your organization’s Legal terms
- Your organization’s Privacy and Cookies

Click these links to validate that the appropriate pages open.
Validate the links in Modern Point of Sale (MPOS) and Cloud Point of Sale (CPOS)

To validate that the links have been added, go to the Settings page. In the About section, click the links to validate that the appropriate pages open.
This topic points you to a report that lists the license codes and configuration keys available in Finance and Operations.

When you purchase Finance and Operations, all functionality is included. By default, some features and functionality that you do not use may be enabled. The administrator should disable the features that are not needed by disabling license codes and configuration keys.

When a license code or configuration key is disabled, the associated module or feature is removed from the user interface. Large sets of functionality, such as modules, are controlled by license codes. Many license codes, in turn, enable configuration keys that allow you to enable and disable functionality at a more detailed level.

To view the report

The License codes and configuration keys report, included with the Technical reference reports, lists each configuration key that is available. The report also indicates the license code and menu items associated with each configuration key.
Cross-company data sharing

This topic provides information about cross-company data sharing. Cross-company sharing is a mechanism for sharing reference and group data among companies in a Finance and Operations deployment. This feature resembles the virtual companies feature in Microsoft Dynamics AX 2012.

What is this feature and how does it work?

Cross-company data sharing lets you replicate (share) reference and group data among companies. Data integrity is verified before replication occurs.

Here are some examples of cross-company data sharing and the basic logic:

- The same payment terms and payment day definitions are used across 15 legal entities.
- The same terms of delivery are used across seven legal entities in three countries/regions.
- Records created, updated, and deleted in any of the companies within the policy will be replicated immediately, across all the companies.
- Fields that are not selected for sharing are maintained in each company and will not trigger any replication.
- As part of enabling a policy, it is optional to copy any existing records.

Cross-company data sharing has the following limitations:

- It can't be used to share transactional data between companies.
- Only reference and group data can be shared, or tables that have specifically been enabled. For example, Data Sharing Type is set to Duplicate.
- It supports replication of fewer than one million total records per job. This total is calculated as the number of shared records × the number of shared companies. The limit is increased to two million records from the Platform Update for version 10.0.10.
- It supports replication for up to 100 companies per policy. The limit is increased to 300 companies from the Platform Update for version 10.0.10.
- Only one level of child relationships is exposed. To protect data consistency, replication doesn't occur if another level is required.
- Fields that reference Financial dimensions, for example Ledger or Default dimension, can't be shared across companies. Dimensions hold a loose foreign key reference to the backing dimension data, which can reference both company-specific and non-company specific data. Determining the appropriate action to be taken for each dimension value has inherent complexity and would require a change from the current implementation, which could dramatically impact performance.
- It can't be used with dual-write.

Policies

Data sharing is managed by defined policies that are saved in data packages. Templates that Microsoft has tested and supports are available as downloadable data packages on Microsoft Dynamics Lifecycle Services (LCS). Policies let you control the following aspects of data sharing:

- The fields that are replicated
- The entities that participate in the replication
- The companies that participates in the sharing

The same company and table can only be in one policy. It is possible to share the same table in more than policy.
This can happen when the limits of records or companies are reached, or to create policies for tables that need to be shared differently for different country/regions.

**NOTE**

Only required foreign key fields are selected by default. Optional foreign keys need to be selected manually to be included. The best practice is to add one or more tables when selecting a foreign key field, unless the table has already been added.

Policy templates that Microsoft has tested and supports are available as downloadable data packages on Lifecycle Services (LCS).

**IMPORTANT**

Although customers can modify the Microsoft data templates that are available from LCS, this scenario isn't supported.

**Conflict resolution**

Validation rules are run when a sharing policy is enabled. If inconsistencies are detected, the user who implements the system can choose which records from which company should win.

**Considerations for successful data sharing**

Several entities in the Microsoft data packages have references that you must consider when you enable the entities. Some data sharing policies can’t be enabled if references don’t match. Other policies can be enabled, but you should use the Find inconsistency checker tool to verify that your data is consistent. Here are some examples:

- The Production group sharing policy has a reference to a company’s chart of accounts. Therefore, all companies that are added to this sharing policy must use the same chart of accounts.
- If you want to enable entities that use number sequences, the number sequence types must be the same across all companies in a sharing policy for those entities.
- Setup options must be the same across the companies that are involved in the sharing policy. Examples of setup options include the setting that specifies whether tax is included by default.

**When should I use cross-company data sharing?**

Use cross-company data sharing for the following business scenarios:

- Sharing of simple reference and group data in a single deployment
- Sharing among companies that have very similar configurations
- Sharing scenarios that have been explicitly tested by Microsoft

Cross-company data sharing isn’t supported for the following scenarios:

- Franchising solutions, where thousands of records are shared across thousands of companies.
- Sharing of transactional records for reporting or management purposes, such as consolidations.
- Sharing across deployments.
- Complex scenarios, such as replication of subtype/supertype tables or tables that have date effectivity rules.
- Tables that do not have a unique index.

**Customer and vendor master data sharing**

Customer and vendor master data sharing allows you to share customer and vendor data across multiple companies. If you would like to be considered for this feature, complete the Data sharing application and contact
With the release of Platform update for version 10.0.12, customer and vendor master data sharing can be enabled using the **Customer and vendor master data sharing** feature in the **Feature management** module. There is no need to complete a survey first. It is important to consider limits in the number of records and companies stated above.

---

**NOTE**

Default dimensions set up against a customer or vendor cannot be shared across companies. When configuring the customer or vendor record for cross-company data sharing, the **DefaultDimension** field is disabled, and cannot be included in the data sharing policy.

---

Default dimensions hold a loose foreign key reference to the backing dimension data, which can reference both company-specific and non-company specific data. Determining the appropriate action to be taken for each dimension value has inherent complexity and would require a change from the current implementation, which could dramatically impact performance.

---

### Download a cross-company data sharing template from LCS

1. Sign in to LCS.
2. On the home page, click **Shared asset library**.
3. In the **Asset type** list, click **Data package**.
4. Click any of the available data package files to download them.

For details about how to use a template, see [Configure financial cross-company data sharing](#).

### Currently supported cross-company data sharing templates

**Additional resources**

Configure financial cross-company data sharing (Task guide)
This topic provides information about maintenance mode in Finance and Operations. When maintenance mode is turned on, it provides a safe way for system administrators to make system changes that might affect system functionality. For example, configuration keys can be enabled or disabled. While maintenance mode is on, only system administrators and users who have the Maintenance mode user role can sign in to the system. By default, maintenance mode is turned off. When maintenance mode is off, you can’t edit the License configuration page.

Turn maintenance mode on and off on sandbox and production environments through Lifecycle Services

You can now turn maintenance mode on and off directly through Lifecycle Services (LCS) on your sandbox and production environments. Refer to the following steps to do this:

1. Go to the environment details page and on the Maintain menu, click Enable Maintenance Mode.
2. In the slider, set Turn maintenance mode on for the environment and select Confirm.
3. A servicing operation will begin and your system will go into maintenance mode.
4. On completion, the environment state will be In Maintenance. At this point, only the system administrator will have access to the environment.
5. After you are done making system-wide changes, you can turn off maintenance mode by clicking Disable Maintenance Mode under the Maintain menu.
6. This will start a servicing operation that takes your environment out of maintenance mode. You can see the progress of the operation in the environment details page.
7. After this is complete, your environment goes back to the Deployed state. Now all users can sign in to the environment.
8. You can check the environment history page to see when the maintenance mode was turned on or turned off. To get to the environment history page, select History and Environment changes on the environment details page.

Turning maintenance mode on and off for your sandbox and production environment is very similar to a servicing operation. If turning maintenance mode on or off fails, you will see options such as Resume, Rollback, and Abort. You also have the option to download the logs to troubleshoot why the operation failed.

Turn maintenance mode on and off in DevTest/Demo environments hosted in Customer's subscription

1. Establish an RDP connection to the developer machine.
2. On the developer machine, sign in to SQL Server by using the credentials for the axdbadmin user from LCS. Then switch to the AXDB database, and run the following command.

   ```sql
   update SQLSYSTEMVARIABLES SET VALUE = 1 where PARM = 'CONFIGURATIONMODE'
   ```

3. Restart the World Wide Web Publishing Service to reset IIS.
4. After the service is restarted, the system will be in maintenance mode.
5. When you've completed your maintenance mode activities, repeat steps 2 and 3, but set the value to 0 in step 2.

**Turn maintenance mode on and off for VHD-based environments hosted by customers**

You can turn on maintenance mode locally by running the following command.

```bash
J:\AosService\PackagesLocalDirectory\Bin\Microsoft.Dynamics.AX.Deployment.Setup.exe --metadatadir J:\AosService\PackagesLocalDirectory --bindir J:\AosService\PackagesLocalDirectory\Bin --sqlserver . --sqldatabase axdb --sqluser axdbadmin --sqlpwd ********--setupmode maintenancemode --isinmaintenancemode true
```

After running the command, you will want to restart the **World Wide Web Publishing Service** to reset IIS. The system will then be in maintenance mode.

The following table describes the parameters that are used in this command.

<table>
<thead>
<tr>
<th>PARAMETER NAME</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>--setupmode maintenancemode</td>
<td>Use this parameter to inform the setup tool that the system will be put into or taken out of maintenance mode.</td>
</tr>
<tr>
<td>--metadatadir</td>
<td>Use this parameter to specify the metadata directory. You should use the default packages directory.</td>
</tr>
<tr>
<td>--bindir</td>
<td>Use this parameter to specify the binaries directory. You should use the default packages directory.</td>
</tr>
<tr>
<td>--sqlserver</td>
<td>Use this parameter to specify the Microsoft SQL Server. For one-box environments, use a period (.).</td>
</tr>
<tr>
<td>--sqluser</td>
<td>Use this parameter to specify the SQL Server user. You should use AOSUser.</td>
</tr>
<tr>
<td>--sqlpwd</td>
<td>Use this parameter to specify the SQL Server password.</td>
</tr>
<tr>
<td>--isinmaintenancemode</td>
<td>Use this parameter to turn configuration mode on or off. Use <strong>true</strong> to turn it on and <strong>false</strong> to turn it off.</td>
</tr>
</tbody>
</table>

**Enable (or disable) configuration keys**

After the instance of Application Object Server (AOS) is restarted, the system will be in maintenance mode. You can then enable configuration keys, as shown in the following screenshot.
If you try to access the system while in maintenance mode, but you aren't a system administrator or a user who has the **Maintenance mode user** role, you may receive an error message. 

You can turn off maintenance mode by running the following command.

```
J:\AosService\PackagesLocalDirectory\Bin\Microsoft.Dynamics.AX.Deployment.Setup.exe --metadatadir J:\AosService\PackagesLocalDirectory --bindir J:\AosService\PackagesLocalDirectory\Bin --sqlserver . --sqldatabase axdb --sqluser axdbadmin --sqlpwd ********* --setupmode maintenancemode --isinmaintenancemode false
```

After running the command, you will want to restart the **World Wide Web Publishing Service** to reset IIS. The system will then be out of maintenance mode.
Pre-configured system accounts are included on deployed environments so that Microsoft can manage and operate the Finance and Operations service and provide specific features to customers. The following table provides information about each account, including the purpose and use case for the account.

### IMPORTANT
Do not delete these system accounts. Deleting these accounts will cause a disruption in key functionality provided by Microsoft.

<table>
<thead>
<tr>
<th>ACCOUNT DETAIL</th>
<th>PURPOSE/USE CASE OF THE ACCOUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Axrunner</td>
<td>This account is used to monitor the health of the environment and provide alerts when necessary.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: This account is deprecated with self-service environments and is no longer used.</td>
</tr>
<tr>
<td>FRServiceUser</td>
<td>This account is the Financial Reporting service user account, which is used by the Management Reporter application for integrations with Finance and Operations.</td>
</tr>
<tr>
<td>RetailServiceAccount</td>
<td>This account is used for Retail services to connect to the Finance and Operations environment.</td>
</tr>
<tr>
<td>SysHealthServiceUser or Axping (depending on the deployed product version)</td>
<td>This account is used to monitor the availability and health of the environment and provide alerts when necessary.</td>
</tr>
</tbody>
</table>
You can automatically export business-to-business (B2B) users to Azure Active Directory (Azure AD).

In the past, B2B users were exported manually to a .csv file. Then the Azure AD tenant administrator had to use this file to manually add the users to Azure AD using the Azure portal.

To enable the automatic export feature, a one-time setup and configuration process must be completed. When the process is completed, you can use the **Provision Azure AD B2B user** workflow task to automatically export B2B users to Azure AD.

The one-time set up and configuration means that you'll need to:

1. Set up a B2B invitation service application in Azure AD.

### Set up a B2B invitation service application in Azure AD

The tenant administrator of your Azure AD tenant will need to complete the following steps.

1. Log on to the [Azure portal](#) as the tenant administrator.
2. Click **Azure Active Directory** > **Properties**.
3. Copy the **Directory ID** (this is the tenant ID) and save it. You will need this later.
4. Click **App registrations** > **New application registration**.
5. Enter the following information, and then click **Create**.
   a. In the **Name** field, enter the name of the application. For example: **B2B admin application**.
   b. In the **Application type** field, select **Web app /API**.
   c. In the **Sign-on URL** field, enter the URL for Finance and Operations.
6. Click the **App registrations** tab, click the newly created application, copy the **Application ID**, and save it. You will need this later.
7. Click **All settings** > **Required permissions** > **Add**.
8. In the **Add API access** pane, do the following:
   a. Click the **Select an API** tab. Click **Microsoft Graph**, and then click **Select**.
   b. In the **Select permissions** tab, select the following **application permissions** and set them to **Yes**:
      - Invite guest users to the organization
      - Read and write directory data
      - Read and write all users’ full profiles
   c. Select the following **delegated permissions** and set them to **Yes**:
      - Invite guest users to the organization
      - Read and write directory data
      - Read and write all users’ full profiles
Configure the B2B invitation service settings

1. Sign in to Finance and Operations as administrator.

3. Select Enabled.

4. Verify that the Tenant ID is the same as the Directory ID (which you noted in step 3 of the previous procedure).

5. In the Client ID field, enter the Application ID (which you noted in step 6 of the previous procedure).

6. Enter the key Value, copied from the above procedure, into the Application Key field.

7. Save the settings.

Now you can start using the Provision Azure AD B2B user workflow task in your workflows to automatically export B2B users to Azure AD.
Data maintenance enables simple scheduling processes that you can run to find or correct data inconsistencies in your environment.

Incorrect data can adversely affect your day-to-day, monthly, and yearly operations. Inconsistencies and errors that come from incorrect data has the potential to halt major events like year-end activities and can even halt your daily revenue streams and affect your organization's decision-making capabilities.

The *Data Maintenance Portal* is a tool that lets system administrators schedule and run various actions that will have a direct effect on the data or the system. Some actions can be scheduled to continuously look for opportunities to fix issues, and others can be run on demand to enact some change on the system. Currently there are three basic types of actions: direct, scanning, and fixing.

### Types of actions

- **Direct actions** can be run on-demand only, and can run tasks directly. Microsoft Support may use direct actions, which could be as simple as clearing a cache without the need for downtime or as complicated as running a reference scanner to aid the support process.

- **Scanning actions** will search your data, a few times a day, looking for problems in the data. The problems found will be reported to Microsoft. There are a number of system actions that may not yet have an automated fix, but will provide valuable data to Microsoft to improve the health of your data. Microsoft may reach out to you regarding problems found through this method.

- **Fixing actions** runs on the same cadence as a scanning action, but when an opportunity is found, it will schedule a fix to the data. Fixing actions are meant to be data idempotent and may not fix all of the data on the first run. We recommend that a fixing action only fixes a subset of data each time it runs. Over time, the data will reach a clean state without exposing a significant load on the system. This type of action may help facilitate an in-place upgrade of your system.

### Control of actions

To access the Data Maintenance Portal, administrators can go to *System administration > Periodic tasks > Data maintenance*. On this page, administrators can see the list of actions that are available, and the latest status of each action. Important information about the action can be found in the right panel. If the action can be scheduled, there will be a button labeled *Schedule* available at the bottom of the page. All actions can be run on demand, prior to being run by the automated schedule, by selecting the *Run now* button. System actions, defined by Microsoft, cannot be disabled or enabled.

**NOTE**

The recurrence of data maintenance processes are handled by the process automation framework as background processes. There are two main types of background processes: one for scanning for opportunities and one for running tasks. For more information, see *Process automation framework development*. 
This topic provides an overview of the elements of role-based security in Finance and Operations.

In role-based security, access is not granted to individual users, only to security roles. Users are assigned to roles. A user who is assigned to a security role has access to the set of privileges that is associated with that role. A user who is not assigned to any role has no privileges.

In Finance and Operations apps, role-based security is aligned with the structure of the business. Users are assigned to security roles based on their responsibilities in the organization and their participation in business processes. The administrator grants access to the duties that users in a role perform, not to the program elements that users must use.

Because rules can be set up for automatic role assignment, the administrator does not have to be involved every time that a user’s responsibilities change. After security roles and rules have been set up, business managers can control day-to-day user access based on business data.

Overview of role-based security

This section provides an overview of the elements of role-based security. The security model is hierarchical, and each element in the hierarchy represents a different level of detail. Permissions represent access to individual securable objects, such as menu items and tables. Privileges are composed of permissions and represent access to tasks, such as canceling payments and processing deposits. Duties are composed of privileges and represent parts of a business process, such as maintaining bank transactions. Both duties and privileges can be assigned to roles to grant access to Finance and Operations.

The following illustration shows the elements of role-based security and their relationships.

Security roles

All users must be assigned to at least one security role in order to have access to Finance and Operations. The security roles that are assigned to a user determine the duties that the user can perform and the parts of the user interface that the user can view.

Administrators can apply data security policies to limit the data that the users in a role have access to. For example, a user in a role may have access to data only from a single organization. The administrator can also specify the level of access that the users in a role have to current, past, and future records. For example, users in a role can be assigned privileges that allow them to view records for all periods, but that allow them to modify records only for the current period.
By managing access through security roles, administrators save time because they do not have to manage access separately for each user. Security roles are defined one time for all organizations. In addition, users can be automatically assigned to roles based on business data. For example, the administrator can set up a rule that associates a Human resources position with a security role. Any time that users are assigned to that position, those users are automatically added to the appropriate security roles.

Security roles can be organized into a hierarchy. The role hierarchy allows the administrator to define a role based on another role. For example, the sales manager role could be defined as a parent role of the manager role and the salesperson role. A parent role automatically inherits the duties, privileges, and conditions that are assigned to its child roles. Therefore, a user who is assigned to the parent role can perform all of the tasks that users in the child roles can perform. A role can have one or more child roles or one or more parent roles.

By default, sample security roles are provided. All functionality is associated with at least one of the sample security roles. The administrator can assign users to the sample security roles, modify the sample security roles to fit the needs of the business, or create new security roles. By default, the sample roles are not arranged in a hierarchy.

**Duties**

Duties correspond to parts of a business process. The administrator assigns duties to security roles. A duty can be assigned to more than one role.

In the security model, duties contain privileges. For example, the **Maintain bank transactions** duty contains the **Generate deposit slips** and **Cancel payments** privileges. Although both duties and privileges can be assigned to security roles, we recommend that you use duties to grant access to Finance and Operations.

You can assign related duties to separate roles. These duties are said to be segregated. By segregating duties, you can better comply with regulatory requirements, such as those from Sarbanes-Oxley (SOX), International Financial Reporting Standards (IFRS), and the United States Food and Drug Administration (FDA). In addition, segregation of duties helps reduce the risk of fraud, and helps you detect errors or irregularities.

Default duties are provided. The administrator can modify the privileges that are associated with a duty, or create new duties.

**Privileges**

In the security model, a privilege specifies the level of access that is required to perform a job, solve a problem, or complete an assignment. Privileges can be assigned directly to roles, however we recommend that you only assign duties to roles. This is so that the privileges are first grouped together into a duty, which makes it easier to maintain.

A privilege contains permissions to individual application objects, such as user interface elements and tables. For example, the **Cancel payments** privilege contains permissions to the menu items, fields, and tables that are required to cancel payments.

By default, privileges are provided for all features in Finance and Operations. The administrator can modify the permissions that are associated with a privilege, or create new privileges.

**Permissions**

Each function, such as a form or a service, is accessed through an entry point. Menu items, web content items, and service operations are referred to collectively as entry points.

In the security model, permissions group the securable objects and access levels that are required to run a function. This includes any tables, fields, forms, or server side methods that are accessed through the entry point.
This topic provides an overview of the security architecture of Finance and Operations.

When you understand the security architecture, you can more easily customize security to fit the requirements of your business. The following diagram provides a high-level overview of the security architecture.

**Authentication**

By default, only authenticated users who have user rights can establish a connection.

Microsoft Azure Active Directory (AAD) is a primary identity provider. To access the system, users must be provisioned into a Finance and Operations instance and should have a valid AAD account in an authorized tenant.

**Authorization**

Authorization is the control of access to Finance and Operations applications. Security permissions are used to control access to individual elements of the program: menus, menu items, action and command buttons, reports, service operations, web URL menu items, web controls, and fields in the Finance and Operations client.

Individual security permissions are combined into privileges, and privileges are combined into duties. The administrator grants security roles access to the program by assigning duties and privileges to those roles.

Context-based security controls access to securable objects. When a privilege is associated with an entry point (such as a menu item or a service operation), a level of access, such as Read or Delete, is specified. The
authorization subsystem detects the access at run time, when that entry point is accessed, and applies the specified level of access to the securable object that the entry point leads to. This functionality helps to ensure that there is no over-permissioning, and the developer gets the access that was intended.

For more information, see Role-based security.

Data security

Authorization is used to grant access to elements of the program. By contrast, data security is used to deny access to tables, fields, and rows in the database.

Use the extensible data security framework to supplement role-based security by restricting access to table records based on security policies. A security permission, as part of a user role, increases the access a user has to data, while a security policy decreases access to data.

For more information, see Extensible data security policies.

 Additionally, the Table Permissions Framework helps protect some data. Data security for specific tables is enforced by Application Object Server (AOS).

Auditing

Auditing of user sign in and sign out is enabled, which means that the system logs when a user signs in or out of the application. A sign out is logged even if the user's session expires or ends.

A system administrator or security administrator can access the audit logs by going to the User log page (System administration > Inquiries > User log).
Encryption at rest

Microsoft uses encryption technology to protect customer data while at rest in an environment’s SQL Server database and Azure Storage.

All instances utilize Microsoft SQL Server Transparent Data Encryption (TDE) and Azure Storage encryption to perform real-time encryption of data when written to the disk at rest.

Finance and Operations apps use server-side encryption using service-managed keys. All key management aspects such as key issuance, rotation, and backup are handled by Microsoft.

In addition to the default encryption at rest provided above, you can use the encryption API available in the Global X++ class. The methods Global::editEncryptedField() and Global::editEncryptedStringField() use the environment-specific data encryption certificate to perform data encryption and decryption. You can use these methods as an additional layer of protection beyond the default encryption at rest technology used for data storage.

Encryption in transit

Connections established between customers and Microsoft datacenters are encrypted, and all public endpoints are secured using industry-standard Transport Layer Security (TLS) 1.2. TLS effectively establishes a security-enhanced browser-to-server connection to help ensure data confidentiality and integrity between desktops and datacenters.

Supported TLS versions

Finance and Operations apps support TLS 1.2 only. Earlier TLS versions, 1.0 and 1.1, are not supported.

Supported cipher suites

Finance and Operations apps only support the following cipher suites:

- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256

- Microsoft SQL Server Transparent Data Encryption (TDE)
- Azure Storage encryption
- Insider tips on development
The session inactivity timeout setting represents the amount of time a user can be inactive before the user’s session times out and closes. It only affects user browser sessions.

You can set the values from 5 minutes to 60 minutes.

This function has a default value of 30 minutes. You can set the value up to 60 minutes, however doing so might cause extra load on the system.

**NOTE**

This feature is available as of Platform update 29.

If you previously set a session inactivity timeout in the web.config (`WebClientStatefulSessionTimeoutInSeconds` key) through a support request, then that old value will still be honored. The change in default will only affect those who had not explicitly set a new session inactivity timeout in the web.config.

To change the value, follow these steps:

1. Select **System administration > Setup > System parameters** to open the **System parameters** page.
2. On the **General** tab, in the **Session management** section, enter a value in the **Session inactivity timeout in minutes** field.
3. Select **Save**.

   If you set the value to greater than 30, you will be prompted to confirm your selection. The confirmation prompt says “Increasing the inactivity session timeout can cause extra load on your system, which can lead to a decrease in performance. Are you sure you want to continue?” The higher the value, the higher the load will be, which can affect negatively system performance. Select **Yes** to save the changes, or **No** to revert to the existing value.

### Alerting users before sessions end due to inactivity

To give users awareness of an impending session suspension due to inactivity and to help prevent users from losing any unsaved changes when this occurs, users will be notified before their sessions are set to be terminated due to inactivity and given an opportunity to reconnect. The notice given to the user is dependent on the **Session inactivity timeout** setting.

- If the **Session inactivity timeout** is more than 30 minutes, the user will see a countdown notification starting **5 minutes** before the session is set to close.
- If the **Session inactivity timeout** is between 10 and 30 minutes, the user will see a countdown notification starting **2 minutes** before the session is set to close.
- If the **Session inactivity timeout** is less than 10 minutes, the user will see a countdown notification starting **30 seconds** before the session is set to close.
Finance and Operations provides a set of rich security reports to help you understand the set of security roles running in your environment and the set of users assigned to each role. In addition to the reports noted in this topic, developers can generate a workbook containing all user security privileges for all roles using Visual Studio > Dynamics 365 > Addins > View related objects and licenses for all roles.

Each of the security reports can be found under System administration > Inquiries > Security. A description of each report is provided below.

### User role assignments

The **User role assignments** report generates a view of the current user role assignments in your system. By default, the report includes all users with roles assigned. You can optionally limit the report to a specific set of users by entering a list of users when generating the report. On the **User role assignments** parameters pane, go to Records to include > Filter. From here you can add or remove filters to the list of users the report will be generated for.

<table>
<thead>
<tr>
<th>Organization type</th>
<th>Operating unit types</th>
<th>Organization name</th>
<th>Organization ID</th>
<th>Grant with children</th>
</tr>
</thead>
<tbody>
<tr>
<td>Legal entity</td>
<td>None</td>
<td>ALL</td>
<td>ALL</td>
<td>No</td>
</tr>
</tbody>
</table>

### Role to user assignments

The **Role to user assignment** report provides an aggregation of role assignments. Expanding a role in the
Security role access

The Security role access report provides a view of the effective permissions for each security role. This report provides a flattened list of permissions grouped by type across all sub-roles, duties, and privileges contained in the role.

The data set backing the Security role access report can be very large, causing the report to take some time to run. If there have been no changes to security roles since the last time the report was run, you can skip building the report by setting the Rebuild collection option to No on the report parameters pane. This will render the report from the existing data set. If it is the first time the report has run, or there could be changes to the role definitions, the Rebuild collection option should be set to Yes. You can optionally limit the roles to be included in the report by adding a filter under Records to include.
Expanding a role shows the category of objects the role has access to. Expanding one of the object types will show a detailed list of each object of that type included in the role.

**Security duty assignments**

The **Security duty assignments** report provides a view of all the duties contained within a role. This report can be configured to run on any collection of roles to ensure that segregation of duties is maintained between roles. By default, the report will include all roles. To limit the roles included, leverage the filtering provided in the **Records to include** section.

</tbody>
</table>
Expanding a role in the **Security duty assignments** report will show each duty assigned to the role, along with details of the duty.

**Batch processing of reports**

Any of the above reports can be set to run as a batch job by going to the **Run in the background** section of the report's parameter pane. Set **Batch processing** to **Yes**, then provide a batch task job name, batch group, and whether the job should run as Private or Critical. The report will then be created when the batch task runs.
Before you can access Finance and Operations apps, you must first be added to the Users page (System administration > Users > Users). Users include internal employees of your organization, or external customers and vendors. Users can be imported or added manually. All users must be correctly licensed for compliant use.

For information about how to buy and license for Finance and Operations apps, see Microsoft Dynamics 365 Licensing Guide.

Assign a license to a user

System admins can assign licenses to users in the Microsoft 365 admin center.

Add an external user in Azure AD and assign a license

External users must be represented in your tenant directory (Azure Active Directory (Azure AD)) so that they can be assigned licenses. Those external users should be added to the tenant in Azure AD as guest users and then assigned the appropriate licenses. A requirement for Finance and Operations apps is that the guest user’s company must use Azure AD. For more information, see Add Azure Active Directory B2B collaboration users in the Azure portal.

Import new users from Azure AD

1. Go to System administration > User > Users.
2. On the Action Pane, select Import users.
3. Select the users to be imported. The list includes Azure AD users that are currently not users in this environment.
4. Select Import users.
5. Select Close.

NOTE

The value for the Company field will be set based on the current session company for the admin. After import, you must assign roles and organizations as applicable. For more information, see Assign users to security roles. Conditionally, it might also be required to associate the user with a Person and to update user options such as language.

Manually add a new user

1. Go to System administration > Users > Users.
2. On the Action Pane, select New.
3. In the User ID field, enter a unique identifier for the user.
4. In the User name field, enter the user’s name.
5. In the Provider field:
   - For internal users, use the defaulted value. For example, your Azure AD tenant prefixed with https://sts.windows.net/.
   - For non-Azure AD users, such as Service-2-Service accounts, enter a basic text value. For example, NA.
value will help avoid incorrect authentication calls that might result in errors if a valid identity provider value is used.

- For external or guest users, add their Azure AD tenant name after https://sts.windows.net/.

6. In the Email field, enter the user’s full Email/User Principle Name.
7. In the Company field, select the default startup company for the user.
8. Select Save.

The values for Identity provider and Telemetry ID will be updated based on a Microsoft graph call, when the user record is saved. The Telemetry ID is based on the user’s Object ID/Security Identifier (SID) in Azure AD.

**NOTE**

After you add a user, you must assign roles and organizations as applicable. For more information, see Assign users to security roles. Conditionally, it might also be required to associate the user with a Person and to update User options such as language.

**Change a user ID**

To change a user ID, you must rename the key in the database. When you change a user ID by using this procedure, all related user settings are modified to use the new user ID. For example, the usage information in the SysLastValue table is updated to reference the new user ID.

**NOTE**

The user ID is the primary key of the user information table. Renaming the primary key can take some time for existing users because all references to the key are also updated in the database.

1. Go to System administration > Users > Users.
2. Select a user in the list and select Options > Record info.
3. Select Rename.
4. Enter a new and unique value for the User ID, and then select OK.
5. Select Yes to confirm.

**Additional resources**

For more options to implement B2B users, see Export B2B users to Azure AD.

For information about preconfigured system accounts, see Preconfigured system accounts.
The user session setting represents the amount of time a user can be signed in before the user’s session expires. After the user’s session expires, the user is required to sign in with their credentials.

The **Maximum session length** can be up to 2,160 hours (90 days), with a minimum of 1 hour.

**NOTE**

This feature is available in public preview as of version 10.0.16. To enable this feature, go to the Feature management page and enable the **(Preview) Enable session management for users** feature.

To change the maximum session length, follow these steps:

1. Go to **System administration > Users > User session management**.
2. Select **New**.
3. In the new row, select the drop-down menu in the **User ID** field.
4. In the user list, select a user.
5. In **Maximum session length (hours)**, enter a value.
6. Select **Save**.

To update the user’s maximum session length:

1. Select the user that you want to update by selecting the row.
2. In **Maximum session length (hours)**, enter a value.
3. Select **Save**.

To delete a user’s maximum session length and replace it with another user’s session:

1. Select the user that you want to delete by selecting the row.
2. In the **User ID** field, select the drop-down menu and select another user.
3. In the **Maximum session length (hours)** column, enter an hour.
4. Select **Save**.

To delete the user’s maximum session length:

1. Select the user that you want to delete by selecting the row.
2. Select **Delete**.

To delete the multiple users’ maximum session length:

1. Select the rows that you want to delete.
2. Select **Delete**.
Import users from Azure Active Directory

11/24/2021 • 2 minutes to read • Edit Online

Import select users

This procedure can be used by system administrators to import select users from Azure Active Directory (Azure AD).

1. User will be imported with the current session company as their default company. Change current company if applicable before importing users.
2. Go to System administration > Users > Users.
3. Click Import users.
4. Select the users that should be imported and select Import users.

After import is completed it will be required to assign roles to users.

Import users in bulk

This procedure can be used by system administrators to import a large number of users from Azure Active Directory. Note that it is not possible to select users when using the Batch import option.

Run the import as a batch job

1. User will be imported with the current session company as their default company. Change current company if applicable before importing users.
2. Go to System administration > Users > Users.
3. Click Batch import.
4. Expand the Run in the background section.
5. Select Yes in the Batch processing field.
6. In the Batch group field, enter or select a value. This is an optional step.
7. Select Yes in the Private field. This is an optional step.
8. Select Yes in the Critical job field. This is an optional step.
9. In the Monitoring category field, select an option.
10. Click OK.

After import is completed, it will be required to assign roles to users.

Run in a sandbox environment

1. Select Batch import.
2. Select OK.
You can set up rules to separate tasks that must be performed by different users. This concept is named segregation of duties. For example, you might not want the same person to acknowledge the receipt of goods and to process payment to the vendor. Segregation of duties helps you reduce the risk of fraud, and it also helps you detect errors or irregularities. You can also use segregation of duties to enforce internal control policies. Complete the following procedure to create a rule. You must be a system administrator to complete the procedure.

2. Click New.
3. In the Name field, type a value for the rule.
4. In the First duty field, click the drop-down button to open the lookup.
5. In the list, find and select the desired record. Select the first duty that is controlled by the rule.
6. In the Second duty field, click the drop-down button to open the lookup.
7. In the list, find and select the desired record. Select the second duty that is controlled by the rule.
8. In the Severity field, select an option. Select the severity of the risk that occurs when the same user or role performs both duties.
9. In the Security risk field, type a value. Enter a description of the security risk.
10. In the Security mitigation field, type a value. Enter a description of the actions that you take to mitigate the security risk. For example, you can mitigate the risk by conducting more detailed reviews of the process, by conducting a monthly managerial review, or by sharing resources with other departments.
11. Click Save.

IMPORTANT
Compliance with the rules for segregation of duties is not verified when you create a rule. You can create a rule that creates a conflict for existing roles. Existing user role assignments can also be in conflict with the new rule. You must validate compliance after you create or modify a rule. For more information, see Identify and resolve conflicts in segregation of duties
This topic explains how to identify and resolve conflicts in segregation of duties. You can set up rules to separate duties that must be performed by different users. This concept is named segregation of duties. When the definition of a security role or the role assignments of a user violate the rules, the conflict is logged. All conflicts must be resolved by the administrator. Complete the following procedure to identify and resolve conflicts.

After a rule has been added, verify that all existing roles are compliant.

2. Select Validate duties and roles. If any roles violate the rules, a message is displayed that contains the name of the role, the role, and the names of the conflicting duties. Conflicting roles must be modified using Security configuration and can't include conflicting duties. If no roles violate the selected rule, a message indicates that all roles comply.

**NOTE**
The validation is only performed for the selected rule. It is important to validate compliance for each rule.

When you create or modify a role, the rules for segregation of duties are automatically enforced. You cannot assign conflicting duties to a role.

Next, verify that all existing role assignments are compliant.

1. Go to System administration > Security > Segregation of duties > Verify compliance of user-role assignments.
2. Select OK. A notification displays the results of the validation. Conflicts are logged on the Segregation of duties unresolved conflicts page.

When you assign users to roles, the rules for segregation of duties are automatically enforced. If you try to assign a user to roles that contain conflicting duties, you receive an error message. You must then resolve the conflict by denying or allowing the additional role assignment. The additional role will be assigned after the assignment is allowed.

**NOTE**
Conflicts are currently not verified for users that are assigned roles based on the Active Directory Domain groups.

View and resolve conflicting user role assignments
1. Go to **System administration > Security > Segregation of duties > Segregation of duties unresolved conflicts**.

2. Select a conflict, and then select one of the following actions:

   - **Deny assignment**: This will deny the assignment of the user to the additional security role. If you deny an automatic role assignment, the user is marked as excluded from the role. The excluded user isn't granted the access associated with the role and can't be assigned to the role until the administrator removes the exclusion.

   - **Allow assignment**: This will override the conflict and allow the user to be assigned to the additional security role. If you override a conflict, you must enter a reason in the **Reason for override** field. All overridden role assignments can be viewed on the **Segregation of duties conflicts** page.

   **NOTE**

   If several conflicts are listed for the same user, select the user record and evaluate assigned roles on the **Users** page. To avoid this conflict, validate each rule after it's added or modified.
Assign users to security roles

To use anything other than common capabilities in Finance and Operations apps, users must be assigned to security roles. You can assign users to roles automatically, based on rules and business data, exclude users from automatic role assignment, or add users to roles manually.

Automatically assign users to roles

This procedure explains how system administrators can automatically assign users to roles, based on business data.

1. Go to Navigation pane > Modules > System administration > Security > Assign users to roles.
2. In the tree, select 'Accounting supervisor'. Select the role that you want to configure the rule for. In this example, select Accounting supervisor.
3. Select Add rule to open the dialog menu.
4. In the Select a query list, find and select the desired record. Select the query to use for this rule.
5. In the Membership rule name list, click the link in the selected row.
6. Select Edit query. Edit the query, as needed.
7. Select OK.
8. Select Run automatic role assignment.
10. Review the roles assigned to various users to confirm that the role assignment query was correct. Adjust and re-run if needed.

Exclude users from automatic role assignment

1. Close the page.
2. Go to Navigation pane > Modules > System administration > Security > Assign users to roles.
3. In the tree, select 'Accounting supervisor'. Select a role. For this example, select Accounting supervisor.
4. In the Users assigned to role menu, select Manually assign / exclude users.
5. In the Assign users to or exclude users from role list, mark the selected row. Select a user.
6. On the Action pane, select Exclude from role.
7. Select Exclude from role to exclude the selected users from the role. To remove exclusions, select the users that you want to remove exclusions for, and then click Reset status. When you remove an exclusion by resetting the user’s status, the user’s role is assigned automatically. However, the user is not immediately assigned to the role or excluded from the role when you reset the status. Instead, the user is either assigned to the role or removed from the role the next time that the rules for automatic role assignment are run.

Manually assign users to roles

Users who are manually assigned to security roles must also be manually removed by the administrator. These users are not removed from roles by rules for automatic role assignment.

1. Go to Navigation pane > Modules > System administration > Security > Assign users to roles.
2. In the tree, select a role, and in the Users assigned to role menu, select Manually assign / exclude users.
3. In the **Assign users to or exclude users from role**, users that have not been assigned the role are listed with the **Assignment mode** set to **None**. Select one or more users that should be assigned the role.

4. On the **Action pane**, select **Assign to role**. The **Assignment mode** is updated to **Manual** and the users now have a new role assigned.
Import or export a customized security configuration by using Data management

11/24/2021 • 2 minutes to read • Edit Online

The topic explains how a customized security configuration can be exported and imported across environments by using the Data management framework. This functionality can be used when, for example, a customized security configuration must be moved from a test environment to a production environment.

The following entities hold the customized, role-based security (that is, privileges, duties, and roles) that has been added or modified by using security configuration:

- Security privilege metadata customization entity
- Security duty metadata customization entity
- Security role metadata customization entity

Export customized security configuration

1. Go to System administration > Workspaces > Data management.
2. Select the Export tile.
3. In the Group name field, enter a name for the group.
4. Set the Generate data package option to Yes.
5. Select Add multiple to open the drop-down dialog box.
6. Filter the entities by setting the following fields:
   - In the Entities field, enter Security.
   - In the Entity category field, select Master.

![Export custom security configuration interface](image-url)
7. In the **Target data format** field, select **Excel**.

8. Select the applicable security customization entities.

9. Select **Add selected**.

   In version 10.0.12 and later, ignore any warning messages about data length. Those messages aren't applicable, because the entities that are included use containers in data package mode.

10. Select **Close**.

11. Make sure that the **Sequence** field is set in the order of the entity dependencies. Privileges should be first, then duties, and finally roles.

12. Select **Export**.

13. Select **Close**.

14. Wait for the job to be completed. Select **Refresh** to view the status.

15. Select **Download package**.

16. Save the package.

**Import customized security configuration**

1. Go to **System administration > Workspaces > Data management**.

2. Select the **Import** tile.

3. In the **Group name** field, enter a name for the group.

4. Select **Add file**.

5. Select **Upload and add**.

6. Find the exported package, and then select **Open**.

   In version 10.0.12 and later, ignore any warning messages about data length. Those messages aren't applicable, because the entities that are included use containers in data package mode.

7. Select **Close**.

8. Select **Import**.

9. Select **Close**.

10. Wait for the job to be completed. Select **Refresh** to view the status.

**Related security configuration entities**

- **SystemSecurityUserRoleOrganizationEntity** – Assignment of organizations to security roles.
- **Security segregation of duties rule** – Segregation of duties rules.
- **Security segregation of duties conflict** – Segregation of duties conflicts. This entity has unresolved conflicts but also reviewed conflicts.

Before you begin

This topic provides information about how to analyze and manage security permission requirements based on a task recording. Before you complete the steps in this topic, you must have a task recording of the business process that you want to analyze. To record a business process, see Task recorder resources.

Manage security for a task recording

2. Open the task recording from its location. Select Open from this PC or Open from Lifecycle Services, and then select Close.
3. This will open the Security menu item details page that lists the security objects required for the process.

**NOTE**
The Action and Output menu items are not included in the list.

4. In the User ID field, select a user. If the user does not have permissions for some menu items, the Missing permissions field will update to Yes.

5. Select Add Reference to see a list of the security objects, including roles, duties, and privileges that grant the missing permission.

6. Select a security object from the list:
   - If Role is selected, select Add role to user. This will open the Assign users to roles page. For more information, see Assign users to security roles page.
   - If Duty is selected, select Add duty to role, select the roles that the duty should be added to, and then select OK.
   - If Privilege is selected, select Add privilege to duties, select the roles that the duty should be added to, and then select OK.
This topic provides an overview of Extensible Data Security (XDS) policies in Finance and Operations apps. XDS allows developers to supplement role-based security by restricting access to table records based on security policies. The query in the policy applies a filter and only records that satisfy the conditions of the filter will be accessible from the restricted tables.

Data security policy components

- **Constrained tables**: The table or tables from which data is filtered or secured. For example, in a policy that secures access to transactions based on customer, the `CustTrans` would be an example of a constrained table.

- **Primary table**: Used to secure the content of the related constrained table. In the example below, the `CustTable` table would be the primary table. The primary table must have an explicit relationship to the constrained tables.

- **Policy query**: Used to secure the constrained tables content using a range condition on the primary table contents. Only records that are included in the range will be accessible. The range can, for example, be based on a specific value for Customer.

- **Context** – Controls the conditions under which a policy is applicable. Two main types of contexts are available:
  - **Role context**: Based on the roles that the user is assigned. There are two sub-options for role context:
    - **RoleName** – Indicates that the security policy is only applied to the application user assigned to the role equal to the value of RoleName.
    - **RoleProperty** – This value is used in combination with the `ContextString` property to specify multiple user roles context. It is applied when the Context String value defined in the `Role Property` field for the policy is the same as the `ContextString` field value for the assigned user roles.
  - **Application context**: Applied if the context string set by the application using the XDS::SetContext API is the same as the value defined in the `Context String` field for the policy.
In the Application Object Tree (AOT), policies and their components are displayed under **Security > Policies**.

### Important considerations

The policy query is added to the WHERE clause, or ON clause, on SELECT, UPDATE, DELETE and INSERT operations involving the specified constrained tables. Unless carefully designed and tested, policy queries can have a significant performance impact. Therefore, make sure to follow simple but important guidelines when developing an extensible data security policy. For more information, see the "Developing efficient extensible data security policies" section in *Developing Extensible Data Security Policies (White paper) [AX 2012]*.

When two or more security policies apply, the intersection (not the union) of the records that are included by each policy are the only records that can be accessed. This means that a record must satisfy all the applicable security policies before access to the record is allowed.

### Additional resources

For information about how to debug policies, create more advanced policies, including chaining of restricted tables, table relations based on expressions and much more please refer to these resources:

- Create a simple security policy
- Developing Extensible Data Security Policies (white paper) [AX 2012]
- Securing Data by Dimension Value by using Extensible Data Security (white paper) [AX 2012]
- Extensible Data Security examples – by Andre Arnaud De Calavon [blog]
- Extensible Data Security (XDS) Framework in D365FO - by Alex Meyer [blog]
This topic explains how to create a simple security policy that secures access to customers and customer groups, based on a range for a customer group.

**Add a new query**

1. In Visual Studio, add a new query, such as XDSQCustGroup10, to your project/solution. The query will be used to restrict data access from the **Constraint** table.

![Add New Item - XDSDemo (SYS) [Application Suite]](image)

2. Right-click **Data Sources**, and select **New Data Source**.
3. In the **Table** field, enter the primary table name **CustGroup**.
4. Right-click **Ranges**, and then select **New Range**.
5. Set the **Enabled** field to **Yes**.
6. In the **Data Source** field, enter the primary table name, in this case, 'CustGroup'.
7. In the **Value field**, enter **10** to restrict access to data where CustGroup has value of 10, by defining the Range for the CustGroup field.
Add a new security policy

1. Add a new security policy, such as XDSCustTableOnCustGroup10.

2. Set **Constrained Table** to **Yes**. This will also secure access to the primary table. In this example this is the **CustGroup** table.

3. Set the **Context Type** field to **RoleName**.

4. Set the **Enabled** field to **Yes**.

5. Set the **Operation** field to **AllOperations**. Other available values for **Operation** include **Select**, **Insert**, **Update**, **Delete**, and **InsertUpdateDelete**.

6. Set **Primary Table** field to **CustGroup**.

7. Set the **Query** field to the name of the query created above, for example ‘XDSQCustGroup10’.

8. Set the **Role Name** field to ‘TradeSalesClerk’. Because **Context Type** is set to RoleName for this policy, it is required to enter the AOT name for a user role.
9. Next, add constrained tables. In this simple example add one table.

   ![Diagram of constrained tables]

   a. Right-click **Constrained tables**, and then select **New > Constrained Table**.

   b. Set **Constrained** to **Yes**.

   c. In the **Name** field, enter the Constrained table, for example ‘CustTable’.

   d. In the **Table Relation** field, enter the relationship to the primary table, in this case ‘CustGroup’.

10. As a final step, it is required that you build and synchronize the solution to activate the policy.
This topic provides an overview of how customers can stay compliant with the user licensing requirements for Finance and Operations apps, such as Microsoft Dynamics 365 Finance, Dynamics 365 Supply Chain Management, and Dynamics 365 Commerce.

The licensing requirements for users are determined by the security roles that are assigned to those users. Security roles are built based on a hierarchy of:

- Sub-roles
- Duties
- Privileges
- Directly referenced securable objects

For more information, see Role-based security.

The licensing requirements for users are determined at the organization or tenant level. This topic is focused on the requirements for a single environment. If you have multiple environments, the requirements must be analyzed across all of them.

A licensing requirement is assigned to every securable object. Examples of licensing requirements include None, Team members, Activity, and Operations. The Operations licensing requirement indicates that a full user license is required. Some privileges are unique to a specific full user license and require a base or attach license for the full user license to be assigned to the user. For more information, see the User license estimator report section later in this topic.

The rest of this topic describes the various tools that you can use to ensure that the actual licensing complies with the expected licensing requirements.

### Roles for selected user FactBox on the Users page

You assign roles to users on the Users page (System administration > Users). You can view license requirements for each role in the Roles for selected user FactBox.

The maximum license requirement determines the actual licensing requirement for a user. If any license...
NOTE
Starting with platform update for version 10.0.15, the required license types are extended to include application specific license types such as Commerce, Finance, and Supply Chain Management. This extension makes it possible to view the actual license requirements when you assign roles to users and when using the Roles for the selected user FactBox. More than one value can be displayed for the required license type.

View permissions page

During security configuration on the Configure security page (System administration > Security > Configure security), you can select any security object, a role, duty, or permissions, and then select View permissions to view all permissions that are currently included and their licensing requirements. The header of the View permissions page shows the required license level.

NOTE
Starting with platform update for version 10.0.15, the required license types are extended to include application specific license types such as Commerce, Finance, and Supply Chain Management. This extension makes it possible to identify the specific security objects that determine the actual license requirements while also configuring security. More than one value can be displayed for the required license type.

User license counts report

The User license counts report (System administration > Inquiries > License) is used to get a count of required licenses per license type (for example, Team members, Activity, and Operations).
The report also provides details about each user and the licensing requirements for each assigned role. Users are listed under the highest license type. If the license requirement is identified as Operations, you must use the User license estimator report to determine the specific full user licensing requirements.

The User counts history report shows total counts per date, but without any details.

**NOTE**

This report depends on the Named user license count reports processing batch job. To determine when the batch was last run, use the Batch job history page.

**User license estimator report**

If the previously mentioned tools have identified that any users require a license of the Operations type, you can use the User license estimator report (System administration > Inquiries > License reports) to get a count of specific licensing requirements for those users. The report includes only those users.

If no privileges that require a specific full user license have been assigned to a user, that user is shown, but no specific full user licenses are marked. That user will be compliant with any full user license that is assigned. In the example in the following illustration, the Database management administrator role is assigned to a user, and no other roles that require a license of the Operations type are assigned.
Based on the licensing guide, this user is compliant with any full user license.

Admin rights apply across the Finance, Supply Chain Management, and Commerce apps. For example, if you have a Finance license, you have the admin rights for Finance, Supply Chain Management, and Commerce.

This principle might apply to several roles that are provided by Microsoft and customizations, based on the included privileges. No specific license is indicated for these users on the **User license estimator** report.

Alternatively, if privileges that require a specific full user license have been assigned to a user, that license is indicated when you look at the licenses that are assigned to the user. In the example in the following illustration, the user must have a base license for Supply Chain Management.

If privileges that require more than one specific full user license have been assigned to a user, those licenses are indicated when you look at the licenses that are assigned to the user. In this case, the user must have a base license for one of the licenses and an attach license for all other full user licenses that are required. In the example in the following illustration, the user must have either a base license for Finance and an attach license for Supply Chain Management, or a base license for Supply Chain Management and an attach license for Finance.

The totals per specific full user license counts aren’t divided into base licenses and attach licenses.

**NOTE**

The total count per specific full user license and evaluation of custom privileges are included starting in the release of the platform update for version 10.0.13. The report can’t separate the base and attach license requirements. Therefore, it lists only the total full user licenses requirements.

**Additional resources**
For information about how to buy and license Finance and Operations apps, see Microsoft Dynamics 365 Licensing Guide.

For information about how to assign licenses to users in the Microsoft 365 admin center, see Assign licenses to users.

Additional user licenses are required when multiple implementation projects exist for the same tenant. For more information, see Multiple LCS projects and production environments on one Azure AD tenant.
This topic explains how you can view the status of independent software vendor (ISV) licenses for Finance and Operations apps, such as Dynamics 365 Finance, Dynamics 365 Supply Chain Management, and Dynamics 365 Commerce.

License codes and configuration keys are part of the ISV licensing model for Finance and Operations apps.

**NOTE**

Configuration keys that are provided by Microsoft aren't part of the licensing model for Finance and Operations apps. The keys are only used to enable and disable functionality.

When an ISV license key and code are installed, the corresponding configuration key will be available and enabled on the License configuration page.

**View ISV license status**

Each ISV solution that is tied to a license runs only when a valid license code exists in the customer's environment. Therefore, if an ISV ties their solution to a license, but the customer doesn't have a valid license code, the solution doesn't run. To prevent the loss of functionality, it's important to track the expiration dates, if applicable, for license codes. To view the expiration dates, go to System administration > Setup > License configuration, and select the License codes tab.

To avoid downtime, review the expiration dates of the license keys, and if applicable, obtain and import new license keys before moving to a new version. The License codes tab shows the expired license codes. The corresponding configuration key won't appear in the Configuration keys tab.

**Additional resources**

For more information about the ISV licensing feature, see Independent software vendor (ISV) licensing.

For more information about how to import ISV licenses into an on-premises deployment, see Independent software vendor (ISV) licensing (on-premises).

For more information about the configuration keys report, see License codes and configuration keys report.
Process automation allows simple scheduling of processes that will be run by the batch server. The updated calendar view of the scheduled work allows end users to view and take action on scheduled and completed work.

Administration

The central administration page for all process automations is found in the System Administration module under the Setup menu. This page will list all automated processes (series) that are set up in the system. It will also allow you to add new process automations directly from this page. After a series is set up, you can manage each series from this list. You can choose to edit the entire series, delete it, view all occurrences in a list view, or disable the series if you would like to pause the scheduled work for a while.

Any processes that are disabled in feature management won’t show when the feature is disabled. Additionally, the process automation scheduling engine won’t schedule any occurrences or background processes for a disabled feature. Re-enabling the feature will cause any scheduled occurrences or background processes in the past to run immediately. The process automation scheduling engine relies on the system batch job, Process automation polling system job to run. The job shouldn’t be altered or tampered with at any time.

Calendar view

One of the key benefits of process automation is the ability to see the scheduled work in a simple calendar view. This view allows you to see work for a week at a time. You’ll see this view on the right side of the Process automation page. It will be populated with the scheduled work for the selected series.
Occurrence changes

Each occurrence can be modified without impacting other occurrences defined by the series that originated them. Occurrences of scheduled work can be edited from the calendar view by selecting the View/Edit button and selecting Occurrence. This page allows you access to all the settings originally shown in the series setup wizard and provides the ability to make a one-off change for the selected occurrence. An occurrence of scheduled work can also be turned off by selecting the Disable button from the calendar view.

Developer documentation

The process automation framework allows developers to extend the process automation framework. The Process automation framework documentation provides information about how you can create custom processes that you require to be run by the batch server scheduled with the process automation wizard and appear in the calendar view automatically.
This topic provides an overview of batch processing.

Many tasks in Finance and Operations can be run as part of batch jobs. For example, batch jobs can include tasks for printing reports, performing maintenance, or sending electronic documents. By using batch jobs, you can avoid slowing down your computer or the server during typical working hours.

The tasks in a batch job can run either sequentially or at the same time. Additionally, you can create dependencies between tasks. In other words, the sequence of tasks can differ, depending on whether an earlier task succeeds or fails.

You can set up recurrence patterns for batch jobs. For example, you can set up a job to process invoices automatically at the end of every month.

To monitor batch jobs, you can set up alerts. Alerts can be sent when the batch job succeeds, fails, or has finished running.

After a batch job has been processed, you can view the history. The history includes any messages that were encountered while the job was running.

Use batch groups to categorize batch tasks and run them on specific servers. The servers in your environment might have different software installed, or they might be available at different times of the day. Batch groups are used to direct batch tasks to the most appropriate server. Tasks in the same batch job can belong to different batch groups.

For example, server A is set up to print reports, and server B is set up to send electronic documents. You can use batch groups to make sure that reporting tasks are run on server A and electronic documents are processed by server B.

For more information, see Batch processing and batch servers.

**Batch functions**

Administrators and Batch managers can perform common tasks including creating and copying batch jobs, changing a batch job user, and specifying a time period in which a job should not execute. For more information about these tasks, see the following topics:

- Create a batch job
- Batch manager security role
- Active batch periods
- Copy a batch job
- Set up alerts
- Enhanced batch forms
- Clean up the batch job history
- Abort an executing batch job
This topic describes batch processing and batch servers, and how to plan for their use.

The batch framework provides an asynchronous, server-based batch processing environment that can process tasks across multiple instances of Application Object Server (AOS).

You should become familiar with the following aspects of the batch framework:

- **A batch job** is a process that is used to achieve a specific goal. A batch job consists of one or more batch tasks.

- **A batch task** is an activity that is run by a batch job. You can add batch tasks that have multiple types of dependencies to a batch job. You can also configure AOS instances to run multiple threads, each of which runs a task. All batch tasks that are waiting to be run can be run by any available AOS instance that is configured as a batch server. To improve throughput and reduce overall execution time, you can define a batch job as many tasks and then use a batch server to run the tasks against all available AOS instances.

- **A batch group** is an attribute of a batch task. A batch group lets the administrator determine or specify which AOS instance runs the task. When you create a new task, it's put in the default batch group. All batch servers are configured to process the default batch group and the waiting tasks from any job. Additionally, you can create a named batch group, and then set an affinity between that batch group and specific AOS instances. After you create this affinity, only the specified AOS instances will process tasks from the named batch group, and those AOS instances will process tasks from the named batch group only. You can also add the default batch group to the configured servers, if that batch group is required.

### Batch server topology planning

The capacity of a batch server is based on the maximum number of threads that can run concurrently on the AOS instance. Each thread runs one batch task. You can add complex dependencies between or among tasks. You can run these tasks in serial steps or parallel steps, depending on the business logic and requirements. All tasks that don't have any dependencies are considered parallel tasks. AOS instances that are configured as batch servers periodically check for tasks that are waiting to be processed. The batch server assigns each parallel task to a thread and starts to process the thread.

You can run multiple threads across multiple AOS instances. Each AOS instance automatically runs multiple threads, depending on that capacity that is defined in the configuration settings. Therefore, parallel tasks from a job can be run on multiple threads across multiple AOS instances.

A batch server checks for available threads one time per minute. Therefore, you might have to wait for a minute before you see that a waiting task is picked up for processing by an available thread.

### Batch server management planning

All batch servers can be managed from a single location.

One typical use of batch servers is to load balance jobs across multiple servers. You can set the number of threads that the batch server will process.

Because batch servers are also active AOS instances that service requests from the client and other associated components, you must carefully determine when an AOS instance should be available to process batches.
Walkthroughs

The following walkthroughs describe how tasks are processed, and how batch groups can be used to associate batch jobs with batch servers.

**Batch processing of dependent tasks**

For this example, you've created a job that is called JOB 1. As the following diagram shows, the job has seven tasks: TASK 1, TASK 2, TASK 3, TASK 4, TASK 5, TASK 6, and TASK 7.

![Diagram of task dependencies](image)

The tasks have the following dependencies:

- TASK 1 is the first task.
- TASK 2 runs when TASK 1 is completed (regardless of the success or failure of TASK 1).
- TASK 3 runs when TASK 2 is successful.
- TASK 4 runs when TASK 2 is successful.
- TASK 5 runs when TASK 2 fails.
- TASK 6 runs when TASK 3 fails.
- TASK 7 runs when both TASK 3 and TASK 4 are successful.

Two batch servers, Batch1 and Batch2, are configured. Each server has a capacity of one thread.

Imagine that Batch1 checks for waiting tasks, assigns TASK 1 to its thread, and starts to run TASK 1. Although
Batch processing that uses batch groups

NOTE

For this walkthrough, we are using Batch1 and Batch2 to explain the concept. Any batch server that has available threads will start to run a waiting task. You must create a batch group to determine or specify which batch job runs on which server.

Batch processing that uses batch groups

This example shows how batch jobs can be processed on specific batch servers.

You have three batch servers: AOS1, AOS2, and AOS3. By default, all the batch servers process tasks from all batch jobs, depending on the number of available threads.

You create a named batch group, BG1, and configure it to run on AOS2 and AOS3. Therefore, tasks from jobs in BG1 will run only on AOS2 or AOS3, depending on the number available threads. AOS1 won't process tasks from jobs in BG1. Likewise, AOS2 and AOS3 will process tasks from BG1 only.

You can configure AOS2 and AOS3 to process tasks from other batch groups. These batch groups include the default batch group.

Batch excessive tasks configuration (Batch throttling)

Batch throttling can prevent excessive tasks by limiting the average number of executions of a certain batch class per minute. The default upper-bound is 60 tasks per minute. After that, batch framework will suspend the execution of classes for the offending class for another minute, to prevent that specific class from monopolizing the system resources.

NOTE

The batch framework is able to detect instances when there are no non-throttled tasks to be scheduled and executed at any given time. When this occurs, the batch will try to fetch batch tasks from the throttled classes queue to prevent resources from being idle.
Create a batch job

A batch job is a group of tasks that are submitted to an Application Object Server (AOS) instance for automatic processing. Batch jobs are run by using the security credentials of the user who created the job. Use the following procedure to create a batch job. The demo data company used to create this procedure is USMF.

Create the batch job

1. Go to Navigation pane > Modules > System administration > Inquiries > Batch jobs.
2. Click New.
3. In the Job description field, type a value.
4. In the Scheduled start date/time field, enter a date and time.
5. Click Save.

Create a recurrence

1. On the Action Pane, click Batch job.
2. Click Recurrence. Use these options to enter a range and pattern for the recurrence.
3. Click OK.

Add alerts

1. On the Action Pane, click Batch job.
2. Click Alerts. Indicate if you want alert messages sent when the batch job ends, has an error, or is canceled.
   Then specify if you want the alerts to be displayed as pop-up messages.
3. Click OK.

Adjust batch job status

1. Go to System administration > Inquiries > Batch jobs.
2. Select the appropriate batch job.
3. On the Action Pane, click Batch job > Functions > Change status.
4. Select the appropriate status:
   - Withhold: Set the batch job as withhold so it is withheld from the batch job scheduler. Equivalent to stop.
   - Waiting: Set the batch job as waiting so it is waiting to be picked up by the batch job scheduler. Equivalent to go.
5. Click OK.
Enable automatic retries on batch jobs

This topic describes how retries are implemented on batch jobs in Finance and Operations apps, and how you can enable automatic retries on batch jobs when transient failures occur. Currently, if Finance and Operations apps experience a brief loss of connection to Microsoft SQL Server, all batch jobs that are running fail. This behavior disrupts business processes. Because connection loss is inevitable in a cloud service, Microsoft is enabling automated retries when failures of this type occur.

IMPORTANT
This feature is available with version 10.0.18 and later.

Metadata

Because not all batch jobs might be idempotent (for example, when a batch runs credit card transactions), retries can’t be enabled equally across all batch jobs. To help ensure that retries can safely be enabled, Microsoft has added metadata to the batch jobs to indicate whether they can automatically be retried. Between versions 10.0.18 and 10.0.19, more than 90 percent of the Microsoft batch jobs have explicitly implemented the BatchRetryable interface, and the isRetryable value has been set appropriately. For any jobs where the BatchRetryable interface isn’t implemented, the default value of isRetryable is false.

Retries

Retries are enabled only for jobs where the BatchRetryable interface is implemented and isRetryable is set to true. In this new functionality, retries occur on any interruption of the SQL Server connection. Microsoft will continue to add retries on other exceptions.

Frequently asked questions

How do retries work for my custom batch jobs?
There is no change to the custom batch jobs. To take advantage of automated retries, explicitly implement the BatchRetryable interface on the custom batch jobs, and set isRetryable to true. Note that you might have to modify the batch jobs to ensure that they are safe to retry.

How do I implement the retryable interface?
Add the following code to your batch class.

For more information, see Final methods and the Wrappable attribute.
I am extending a Microsoft batch that is retryable, but my batch job isn't retryable. Will the retry be triggered?

Provided that `isRetryable` is set to `false` for the extended job, the job won't be retried.

I mistakenly marked my custom job as retryable. Can I override without taking another code change?

Yes. You can go to `System administration > Setup > Batch class configuration overrides` to unregister your class from being retried when SQL Server connection failures occur, without having to go through a code change. On the `Batch class configuration overrides` page, you must create a new record and add the batch class that you want to unregister. You can use this feature to react quickly to changes that are required. The best practice recommendation is to make sure that the code is updated.

My batch jobs are designed to run multithreaded. How do I implement retries?

If your custom batch process is designed to run in multithreading (that is, if you're creating multiple tasks and adding runtime tasks), you must implement the `BatchRetryable` interface in both the main controller and the task controller.

What is the best practice for the execution time for a batch job?

A batch job that has a shorter execution time is more likely to be successfully completed. Therefore, the need for a retry is avoided.

What is the best practice for the transaction size for a batch job?

A batch job that has a smaller transaction size reduces the amount of work that can be lost because of a transient failure. Therefore, the need for a retry won't drastically increase the total execution time.

What does idempotent mean for a batch job?

In this context, *idempotent* means that a retry won't change or affect the overall result. For example, something should be done only one time and won't be done more than one time. Therefore, something that is done in the original run won't be done again during the retry.

What is the maximum number of retries that `BatchRetryable` supports, and what is the retry interval?

`MaxRetryCount` specifies the number of retries that will be applied to a task, regardless of the type of exception that occurs. If a task fails, the batch platform evaluates the number of times that it has been retried. If the number is less than the value of `MaxRetryCount`, the task is put back into a ready state so that it can be picked up again.

The `BatchRetryable` interface starts after five seconds and stops retrying after the interval time reaches five
minutes. (Interval time increases in the following way: 5, 8, 16, 32, and so on.)

**Can I change the maximum number of retries and the retry interval?**

The **BatchRetryable** interface enables transient SQL connection issues to be handled. It's mainly controlled by the framework. Customers can't update setting for **BatchRetryable**, such as the maximum number of retries and the retry interval.
When you want to create the same jobs for different legal entities, you can use the copy batch job functionality to copy an existing batch job and the batch tasks, including recurrences.

You can set the description, company, schedule start date and time, the recurrence, and the run by account at the same time. When you copy the batch job, any alerts and dependencies from the source job will also be copied.

NOTE
This feature is available as of Platform update 20.

Copy a batch job

Complete the following steps to copy a batch job.

1. Click System administration > Inquiries > Batch jobs.
2. Select the job that you want to copy, and on the Action Pane, click Batch Job > Copy batch job.

4. Enter or add any changes. If you set View tasks to Yes, when you click OK you will go directly to the Batch tasks page for the copied job.
Enable the batch job

Complete the following steps to enable a batch job.

1. On the **Batch job** page, on the Action Pane, click **Batch job > Change status**.
2. Select the **Waiting** status, and then click **OK**.
With the release of Platform update 21, an additional level of control over when batch jobs execute is now available. Previously, it was only possible to schedule a batch job to execute every hour for a specified number of hours or until a given date. Administrators can now provide information for an additional active period, such as in the following scenarios:

- Specifying time ranges during which jobs within a batch group can start execution.
- Selecting to run batch jobs outside of office hours only.
- Setting the recurrence for anytime within the active period. For example, you administrator might select to run the batch jobs every hour, but only between the hours of 6:00 PM and 8:00 AM.

**NOTE**
This feature is available as of Platform update 21.

### Set up active periods for batch jobs

1. Go to **System administration > Setup > Active periods for batch jobs**.
2. Enter the name of the batch job, and specify start and end dates that the batch job is active.
3. Click **Save**.

### Assign active periods to batch jobs

1. Go to **System administration > Inquiries > Batch jobs**.
2. Select the batch job that you want to assign a period to, and click **Edit**.
3. In the **Active period** field, select the active period that you want to assign, and then click **Save**.
Microsoft Dynamics 365 Finance version 10.0.12 includes a Daylight Saving Time support for batch job active periods feature that can be turned on in Feature management. This feature introduces daylight saving time (DST) support for the active periods for batch jobs and lets users associate their active periods with different time zones.

**NOTE**

This feature is a one-way feature. In other words, it can't be turned off after it's turned on.

When this feature is turned on, the following changes occur:

- On the Active periods for batch jobs page, a Timezone field is added for each active period. This field specifies the time zone that the active period uses. By default, every active period initially uses the Coordinated Universal Time (UTC) time zone.

- The start and end times of existing active periods are adjusted according to the UTC time zone. Although the active periods will continue to start and end at the same times that they previously started and ended, the times that are shown might change if the user's preferred time zone isn't UTC.

- Active periods will follow the DST adjustments of the time zones that they are associated with.
Batch manager security role

Before Platform update 20, users needed to be assigned to the system admin or IT admin security role to manage batch jobs. With the release of Platform update 20, there is a more targeted role, Batch manager. With this security role, a user now has permissions to copy batch jobs, change who will execute jobs, and specify the time ranges during which jobs can execute. The Batch maintain security privilege is part of the Batch manager security role and it allows a user to create an ad hoc batch job and grant privileges to other users.

NOTE
This feature is available as of Platform update 20.

Assign the Batch manager role to a user

Complete the following steps to assign the Batch manager security role to a specific user.

1. Select System administration > Security > Assign users to roles.

![Assign users to roles screenshot](image1)

2. Select Batch Job Manager, and on the left pane, select Manually assign/exclude user.

![Manually assign/exclude user screenshot](image2)

3. Select a user from the list, and then select Assign to role.
4. Close the page.

Run by user

The run by user functionality allows Batch managers to specify a user to run the batch job. This functionality is useful when you want to change the user who is currently assigned to run the job or if you want to quickly set a
user while copying the batch jobs from one company to another. You can also use this functionality to copy batch jobs.

Alerts form a notification system for critical events in Finance and Operations. You can use alerts to stay informed about events that you want to track during the workday. You can set up a set of alert rules so that you're alerted when a batch job ends, ends in error, or is canceled. You can select whether the alerts are emailed to you or appear as notifications in the Action center. Alerts can be set up per batch job and per user.

**Set up alerts for batch enhanced forms**

Follow these steps to set up alerts for batch enhanced forms.

1. Go to **System administration** > **Inquiries** > **Batch jobs**.

2. Select a batch job in the list, and then, on the Action Pane, select **Alerts**.

3. In the **Batch job alerts** dialog box, configure the alerts, and then select **OK**.

4. Check the Action center for alert notifications.
Set up alerts for batch legacy forms

Follow these steps to set up alerts for batch legacy forms.

1. Go to System administration > Inquiries > Batch jobs.

2. Select a batch job in the list, and then, on the Action Pane, on the Batch job tab, select Alerts.

3. In the Batch job alerts dialog box, configure the alerts, and then select OK.

NOTE
To receive email notifications, in the Batch job alerts dialog box, set the Email option to Yes.
You can open an enhanced detail transaction form by selecting the job ID for a batch job. The enhanced form provides a header and lines that summarize the batch tasks and constraints that are related to the selected batch job.

Switch to the enhanced form

Follow these steps to switch to the enhanced form.

1. Go to System administration > Inquiries > Batch jobs.

You're notified about the enhanced form. The notification shows the location of the Switch to enhanced form button on the Action Pane.

2. Select Switch to enhanced form.

To switch back to the unenhanced form, select Switch to legacy form on the Action Pane of the enhanced form.
When you run a batch job, a history is recorded. This history can be used to monitor the correct execution of jobs. However, when several batch jobs have been created, especially batch jobs that have a high recurrence, lots of batch job history entries are generated. Too many entries in the history table can negatively affect the performance of future jobs.

Two pages that have been added to the System administration module make it easy to clean up the batch job history:

- Batch job history clean-up
- Custom batch job history clean-up

We recommend that you regularly clean up the batch job history, and that you do this cleanup outside of business hours.
Follow these steps to quickly clean up all history entries that are older than a specified number of days.

1. On the Periodic tasks in System administration module, select Batch job history clean-up.
2. In the History limit (days) field, specify the number of days to keep a history of batch jobs.
3. Select OK.

**Batch job history clean-up.**

<table>

</tbody>
</table>

**Run in the background**

Batch job history clean-up (custom)

The custom batch job lets you to apply additional filtering, based on criteria such as status, job description, company, or user. You can also add other filter criteria by selecting the **Filter** button.

1. On the Periodic tasks in System administration module, select Batch job history clean-up (custom).
2. In the History limit (days) field, specify the number of days to keep a history of batch jobs.
3. On the Records to include FastTab, specify any filter criteria that you require, and then select **OK**.
4. Select **OK**.

NOTE
This feature is available as of Platform update 27.

Sometimes canceling a batch job can take a long time if already executing tasks will take a long time to finish. This option provides a system administrator or batch job manager with the ability to cancel already executing tasks for jobs that are in the process of being canceled. This provides a much faster mechanism to cancel a long running job that is impacting system usage elsewhere.

NOTE
It is important to note that this feature should be used with caution. When you cancel a running process, it is an inherently unsafe action that can lead to data corruption, resulting in either orphaned or incomplete data. This action should only be used to mitigate other issues caused by the running tasks.

Complete the following steps to immediately cancel the running task.

1. Go to System administration > Inquiries > Batch jobs.
2. Select a batch job that has a Status of Canceling.
3. On the Batch tasks tab, select Abort on the task, and then select OK.

Enhanced cancellation feature

Starting in version 10.0.16, an enhancement to the batch cancellation functionality has been introduced. Upon confirmation, this will restart the batch server currently running the batch tasks that you are attempting to cancel. This makes the functionality more resilient to limitations, and ensures that tasks of the job you are trying to cancel are truly preempted.

To use the new functionality, refer to the following steps:

1. Make sure you are running version 10.0.16 or later, or have the necessary quality package installed.
2. Enable the Enhanced batch abort feature in the Feature management workspace.
3. Follow the same instructions to cancel an executing batch job.

You will be prompted that the batch server, which is running the canceling tasks, will be restarted. This can potentially disrupt a list of other batch jobs. You must proceed in order to end the canceling tasks.
If you do not want to cancel other running batch jobs on the server and would prefer the old behavior of canceling a single task and not all the jobs running, you can turn off the Enhanced batch abort feature in the Feature management workspace and try to cancel the executing batch job again.
This topic provides information about the Batch OData application programming interface (API) and explains how you can use Open Data Protocol (OData) to reschedule a job.

In the existing Finance and Operations batch processing functionality, if some types of job errors can be retried (either with or without any changes, based on the interpretation of the error), they must be manually rerun from the batch. For jobs that are scheduled to be run during off-peak times to avoid active business hours for customers, monitoring failures and re-triggering the jobs requires either 24/7 support or a wait time until users resume work during normal business hours.

Current available automation (business events integration)

Business event capabilities enable customers to configure notifications about changes in state (started, failed, finished, or canceled) for batch jobs. Integration with Microsoft Power Automate lets customers capture information about affected jobs without having to sign in to the system. However, manual intervention is required if any action must be taken based on the business events.

For information about how to configure batch events, see Batch business events.

End-to-end automation

In version 10.0.22, the batch functionality now exposes an OData API that can be used to requeue batch jobs. Customers can use the OData endpoint to requeue batch jobs that are in a terminal state. This feature can be integrated with any automation by using Power Automate, custom APIs, and so on.

Automate requeuing of failed batch jobs by using OData API

The Batch OData endpoint lets users consume and automate the end-to-end process to reschedule a batch job by using Power Automate or custom API. It supports updates of the batch job status from a started, failed, finished, or canceled state to a waiting state, based on business requirements.

- **Service endpoint:**
  https://<org url>/data/BatchJobs/Microsoft.Dynamics.DataEntities.SetBatchJobToWaiting

- **Method type:** POST

- **Header:**
  - **Authorization:** Bearer <Bearer token for authentication>
Content-Type: application/json

Body:

```
{
   "batchJobId":<BatchJobId>
}
```

Sample response:

```
{
   "ResponseStatusCode":200,
   "IsSuccess":true,
   "Batch JobId":<BatchJobId>,
   "ExceptionDetails":",
   "reponseMessage":"Status of supplied BatchJobId: *********** is Successfully updated to waiting state"
}
```

Here is an explanation of the elements of the response output:

- **ResponseStatusCode** – A standard HTTP response code, based on the execution of the action.
- **IsSuccess** – A Boolean value that indicates overall success or failure.
- **BatchJobId** – The ID of the input batch job.
- **ExceptionDetails** – Details about any exception that occurred during execution.
- **ReponseMessage** – The success message.
This topic describes how you can use Optimization advisor to help ensure optimal configuration of Finance and Operations.

**Overview**

Incorrect configuration and setup of a module can adversely affect the availability of application features, system performance, and the smooth operation of business processes. The quality of business data (for example, the correctness, completeness, and cleanliness of the data) also affects system performance, and an organization's decision-making capabilities, productivity, and so on.

The **Optimization advisor** workspace is a tool that lets power users, business analysts, functional consultants, and IT support functions identify issues in module configuration and business data. Optimization advisor suggests best practices for module configuration and identifies business data that is obsolete or incorrect.

Optimization advisor periodically runs a set of best practice rules. A default set of rules is available, however users can also create rules that are specific to their customizations, solutions from independent software vendors (ISVs), and business data. For more information about how to create rules, see [Create rules for Optimization advisor](#).

When a violation of a rule is detected, an optimization opportunity is generated and appears in the **Optimization advisor** workspace. A user can take appropriate corrective action directly from the **Optimization advisor** workspace.

Opportunities can be company-specific or cross-company, depending on the type of setup and data that is being validated. Cross-company opportunities can be viewed from all companies. To view the opportunities for a specific company, you must first select the company.

Standard security policies apply to optimization opportunities. For example, the optimization opportunities that are related to configuration of the **Warehouse management** module are visible only to users who have access to Warehouse management and can change its setup.

When you take action on some optimization opportunities, the system calculates the impact of the opportunity in terms of the reduction in the runtime of business processes. Unfortunately, this feature isn't available for all optimization opportunities.

To learn more about Optimization advisor, watch the short [Optimization advisor in Dynamics 365 for Finance and Operations video](#).

**Optimization rules**

To view the complete list of Optimization advisor rules and to see how often the rules are evaluated, go to **System administration > Periodic tasks > Maintain diagnostics validation rule**. Only rules that have a status of **Active** are evaluated. The evaluation frequency can be set to **Daily**, **Weekly**, **Monthly**, or **Unscheduled**.

To trigger the evaluation of unscheduled rules, or to reevaluate periodic rules outside their predefined schedule, go to **System administration > Periodic tasks > Schedule diagnostics validation rule**. Then, in the **Diagnostic rule validation** dialog box, select an evaluation frequency. All rules that have the specified frequency will be reevaluated.
The current set of optimization rules can be divided into the following categories.

**Module configuration and setup**

The setup of Warehouse management is a complicated process. To make the process easier, some rules have been introduced to help validate the correctness of the setup. For example, one rule validates the setup of warehouse location directives for fixed product variant locations for sales orders and transfer orders.

Additionally, some rules check whether features that have been enabled are actually used. For example, one rule determines whether you’re using the Master planning module. If the rule determines that you aren’t using the module, an optimization opportunity is generated to suggest that you turn off the planning processes.

**System configuration**

If specific functionality that is controlled by a configuration key isn’t used, an optimization opportunity is generated to suggest that you disable the configuration key. Examples of configuration keys include Catch weight, Budget planning, Project, and Approved vendor list.

**Business data consistency and cleanup**

If master data isn’t correct (for example, if you have unit of measure conversions for units that haven’t been defined, or if you have unit of measure conversions that have a division by 0 [zero]), an optimization opportunity is generated to suggest that you correct the data.

If you have too many batch job history entries, obsolete items, closed on-hand entries for warehouse enabled items, and so on, or if those entries and items are too old, optimization opportunities are generated to suggest that you clean up the data. By keeping your data clean, you can help improve overall system performance.

**Best practices**

If you aren’t running some business processes according to best practices (for example, if you run inventory pre-closing before the inventory is closed, or if you use the scheduled batch for subledger journal batch transfer), optimization opportunities inform you about the best practice and ask that you follow it.

**Optimization opportunities**

To view the optimization opportunities that are generated during the evaluation of optimization rules, open the Optimization advisor workspace.

In this workspace, you can view more information about an opportunity by selecting More information. If you want the system to take action and correct the setup, clean the data, and so on, so that you don’t have to open the corresponding pages yourself, select Take action.

There is no workflow for optimization opportunities. After you select Take action or use a navigation path that is provided in the More information dialog box, the optimization opportunity disappears from the list. If the corrective action doesn’t completely resolve an issue, the opportunity will be generated again the next time that the rule is evaluated.

If an opportunity doesn’t apply to your role, you can select Hide from my list. Even if the rule behind this opportunity is triggered again later, you won’t see the opportunity in your list.

To deactivate the evaluation of specific rules, select the opportunity that was generated by the rule, and then select Deactivate analysis.

**Additional resources**

Create rules for Optimization advisor

Optimization advisor in Dynamics 365 for Finance and Operations (Video)
This topic explains how to create new rules for Optimization advisor. For example, you can create a new rule that identifies which Request for Quotations (RFQ) cases have an empty title. Using titles on cases makes them easily identifiable and searchable. While quite simple, this example shows what can be achieved with optimization rules.

A rule is a check on application data. If the condition that the rule evaluates is met, opportunities to optimize processes or improve data are created. The opportunities can be acted upon and, optionally, the impact of the actions can be measured.

To create a new rule for the Optimization advisor, add a new class that extends the SelfHealingRule abstract class, implements the IDiagnosticsRule interface, and is decorated by the DiagnosticRule attribute. The class must also have a method decorated with the DiagnosticsRuleSubscription attribute. By convention, that is done on the opportunityTitle method, which will be discussed later. This new class can be added to a custom model with a dependency on the SelfHealingRules model. In the following example, the rule being implemented is called RFQTitleSelfHealingRule.

```java
[DiagnosticsRule]
public final class RFQTitleSelfHealingRule extends SelfHealingRule implements IDiagnosticsRule
{
    
}
```

The SelfHealingRule abstract class has abstract methods that must be implemented in inheriting classes. The core is the evaluate method, which returns a list of the opportunities identified by the rule. Opportunities can be per legal entity or can apply to the whole system.
protected List evaluate() {
    List results = new List(Types::Record);
    DataArea dataArea;
    while select id from dataArea
        where !dataArea.isVirtual
    {
        changecompany(dataArea.id)
        {
            container result = this.findRFQCasesWithEmptyTitle();
            if (conLen(result) > 0)
            {
                SelfHealingOpportunity opportunity = this.getOpportunityForCompany(dataArea.Id);
                opportunity.EvaluationState = SelfHealingEvaluationState::Evaluated;
                opportunity.Data = result;
                opportunity.OpportunityDate = DateTimeUtil::utcNow();
                results.addEnd(opportunity);
            }
        }
    }
    return results;
}

The method shown above loops over companies and selects RFQ cases with empty titles in the findRFQCasesWithEmptyTitle method. If at least one such case is found, then a company-specific opportunity is created with the getOpportunityForCompany method. Notice that the field Data in the SelfHealingOpportunity table is of type Container, and can therefore contain any data relevant to the logic specific to this rule. Setting OpportunityDate with the current timestamp registers the time of the latest evaluation of the opportunity.

Opportunities can also be cross-company. In this case, the loop over companies is not necessary and the opportunity must be created with the getOpportunityAcrossCompanies method.

The following code shows the findRFQCasesWithEmptyTitle method, which returns the IDs of the RFQ cases that have empty titles.

private container findRFQCasesWithEmptyTitle()
{
    container result;
    PurchRFQCaseTable rfqCase;
    while select RFQCaseId from rfqCase
        where rfqCase.Name == ''
    {
        result += rfqCase.RFQCaseId;
    }
    return result;
}

Two more methods that must be implemented are opportunityTitle and opportunityDetails. The former returns a short title for the opportunity, the latter returns a detailed description of the opportunity, which can also include data.

The title returned by opportunityTitle appears under the Optimization opportunity column in the Optimization advisor workspace. It also appears as the header of the side pane showing more information.
about the opportunity. By convention, this method is decorated with the `DiagnosticsRuleSubscription` attribute, which takes the following arguments:

- **Diagnostics area** – An enum of type `DiagnosticsArea` that describes what area of the application the rule belongs to, such as `DiagnosticsArea::SCM`.

- **Rule name** – A string with the rule name. This will appear under the Rule name column in the Diagnostics validation rule form (DiagnosticsValidationRuleMaintain).

- **Run frequency** – An enum of type `DiagnosticRunFrequency` that describes how often the rule should be run, such as `DiagnosticRunFrequency::Daily`.

- **Rule description** – A string with a more detailed description of the rule. This will appear under the Rule description column in the Diagnostics validation rule form (DiagnosticsValidationRuleMaintain).

The `DiagnosticRuleSubscription` attribute is required for the rule to work. Typically, it is used on `opportunityTitle`, but it can decorate any method of the class.

The following is an example implementation. Raw strings are used for simplicity, but a correct implementation requires labels.

```java
[DiagnosticsRuleSubscription(DiagnosticsArea::SCM,
    'Assign titles to Request for Quotation cases',
    DiagnosticRunFrequency::Daily,
    'This rule detects Requests for Quotation with empty titles.')]
public str opportunityTitle()
{
    return 'Assign titles to Request for Quotation cases';
}
```

The description returned by `opportunityDetails` appears on the side pane showing more information about the opportunity. This takes the `SelfHealingOpportunity` argument, which is `Data` field that can be used to provide more details about the opportunity. In the example, the method returns the IDs of the RFQ cases with an empty title.

```java
public str opportunityDetails(SelfHealingOpportunity _opportunity)
{
    str details = '';
    container opportunityData = _opportunity.Data;
    int affectedRFQCasesCount = conLen(opportunityData);

    if (affectedRFQCasesCount != 0)
    {
        details = 'The following Request for Quotation cases have an empty title:
';
        for (int i = 1; i <= affectedRFQCasesCount ; i++)
        {
            PurchRFQCaseId rfqCaseId = conPeek(opportunityData, i);
            details += rfqCaseId + '
';
        }
    }

    return details;
}
```

The two remaining abstract methods to implement are `provideHealingAction` and `securityMenuItem`.

`provideHealingAction` returns true if a healing action is provided, otherwise, it returns false. If true is returned,
the method `performAction` must be implemented, or an error will be thrown. The `performAction` method takes a `SelfHealingOpportunity` argument, in which the data can be used for the action. In the example, the action opens the `PurchRFQCaseTableListPage`, for manual correction.

```java
public boolean providesHealingAction()
{
    return true;
}

protected void performAction(SelfHealingOpportunity _opportunity)
{
    new MenuFunction(menuItemDisplayStr(PurchRFQCaseTableListPage), MenuItemType::Display).run();
}
```

Depending on the specifics of the rule, it might be possible to take an automatic action using the opportunity data. In this example, the system could generate titles for RFQ cases automatically.

`securityMenuItem` returns the name of an action menu item such that the rule is only visible to users who can access the action menu item. Security might require that specific rules and opportunities are accessible only to authorized users. In the example, only users with access to `PurchRFQCaseTitleAction` can view the opportunity. Notice that this action menu item was created for this example, and was added as an entry point for the `PurchRFQCaseTableMaintain` security privilege.

```
public MenuName securityMenuItem()
{
    return menuItemActionStr(PurchRFQCaseTitleAction);
}
```

The method `performAction` must be implemented, or an error will be thrown. The `performAction` method takes a `SelfHealingOpportunity` argument, in which the data can be used for the action. In the example, the action opens the `PurchRFQCaseTableListPage`, for manual correction.

```
public boolean providesHealingAction()
{
    return true;
}

protected void performAction(SelfHealingOpportunity _opportunity)
{
    new MenuFunction(menuItemDisplayStr(PurchRFQCaseTableListPage), MenuItemType::Display).run();
}
```

Depending on the specifics of the rule, it might be possible to take an automatic action using the opportunity data. In this example, the system could generate titles for RFQ cases automatically.

`securityMenuItem` returns the name of an action menu item such that the rule is only visible to users who can access the action menu item. Security might require that specific rules and opportunities are accessible only to authorized users. In the example, only users with access to `PurchRFQCaseTitleAction` can view the opportunity. Notice that this action menu item was created for this example, and was added as an entry point for the `PurchRFQCaseTableMaintain` security privilege.

```
public MenuName securityMenuItem()
{
    return menuItemActionStr(PurchRFQCaseTitleAction);
}
```

After the rule has compiled, execute the following job to have it display in the user interface (UI).

```
class ScanNewRulesJob
{
    public static void main(Args _args)
    {
        SysExtensionCache::clearAllScopes();
        var controller = new DiagnosticsRuleController();
        controller.runOperation();
    }
}
```

The rule will display in the Diagnostics validation rule form, available from System administration > Periodic tasks > Maintain diagnostics validation rule. To have it evaluated, go to System administration > Periodic tasks > Schedule diagnostics validation rule, select the frequency of the rule, such as Daily. Click OK. Go to System administration > Optimization advisor to view the new opportunity.

The following example is a code snippet with the skeleton of a rule including all the required methods and attributes. It helps you get started with writing new rules. The labels and action menu items that are used in the example are only used for demonstration purpose.
public final class SkeletonSelfHealingRule extends SelfHealingRule implements IDiagnosticsRule
{

    public str opportunityTitle()
    {
        // Return a label with the title of the opportunity
        return "$SkeletonRuleLabels:SkeletonOpportunityTitle";
    }

    public str opportunityDetails(SelfHealingOpportunity _opportunity)
    {
        str details = "";
        // Use _opportunity.data to provide details on the opportunity
        return details;
    }

    protected List evaluate()
    {
        List results = new List(Types::Record);
        // Write here the core logic of the rule
        return results;
    }

    public boolean providesHealingAction()
    {
        return true;
    }

    protected void performAction(SelfHealingOpportunity _opportunity)
    {
        // Place here the code that performs the healing action
        // To open a form, use the following:
        // new MenuFunction(menuItemDisplayStr(SkeletonRuleDisplayMenuItem), MenuItemType::Display).run();
    }

    public MenuName securityMenuItem()
    {
        return menuItemActionStr(SkeletonRuleActionMenuItem);
    }
}

For more information, watch the short YouTube video: Optimization advisor in Dynamics 365 for Finance and Operations
Lifecycle Services (LCS) has a feature called **Report production outage**. This feature is available to all customers who have purchased one or more Dynamics 365 Finance and Operations apps and have implementation projects with a production environment deployed in LCS. This feature provides a quick and effective channel to escalate issues to Microsoft Support in the event that the services in a production environment are degraded or become unavailable.

Following mutually inclusive conditions, a production outage can be defined as one or more system-wide issues on a live production environment that impact multiple users and prevent your business from performing daily operations.

**Reporting flow**

The following list shows the order in which an issue should be handled:

1. In a live production environment, a customer experiences an outage or other situation with prevents business from continuing.
2. The customer reports a production outage issue by using the LCS Support portal.
3. The customer selects a production outage issue and provides additional information.
4. A Microsoft support engineer acknowledges the production outage ticket within 30 minutes of submission and begins to immediately collaborate with stakeholders to investigate and resolve the issue.
5. A support engineer contacts the customer to provide a status update.

**Access and availability**

All users who have been added to a customer’s implementation project have access to this feature. This includes project owners, organization admins, team members, and environment managers.

This feature is available for:

- Dynamics 365 Finance
- Dynamics 365 Supply Chain Management
- Environments that are managed by Microsoft
- A production environment in the LCS project
- All support plans

**Report a production outage**

To report a production outage, follow these steps:

1. Log in to your LCS project.
2. From the hamburger menu, click **Support**.
3. On the **Submitted To Microsoft** tab, click **Report production outage**.

4. Confirm the production outage, select the outage scenario from the drop-down list, and then click **Continue**.
5. Add a title and details about the outage, and then click **Next**.
6. Provide contact information, and then click **Next**.
7. Click **Done**.

If you're unable to report a production outage in LCS, **phone support** is available.

**NOTE**

If you don't see your situation listed in the outage scenarios, enter a support incident through LCS. During the initial investigation by a Microsoft support engineer, if it is found that the situation does not meet the current list of production outage scenarios, the support incident will be transferred to the correct support team and service-level agreement (SLA) based on your current support plan.
Database logging provides a way to track specific types of changes to the tables and fields in Finance and Operation apps. Changes that can be tracked include insert, update, delete, and rename key operations. When you configure logging for a table or field, a record of every change to that table or field is stored in the database log table, sysdatabaselog, in the environment database.

Database logging can be used for these purposes:

- Create an auditable record of changes to specific tables that contain sensitive information.
- Monitor the use of electronic signatures. By default, all transactions that have been signed by using electronic signatures are logged.

Database logging is intended to track individual transactions. It isn't intended to track automated transactions that are run in batch jobs.

### Security for database logging

Database logs can contain sensitive data. By default, any user who has database access can query the database log table (sysdatabaselog) by using X++ or alerts, or by querying the database directly. To help protect data, you should restrict permissions on the sysdatabaselog table for on-premises deployments.

### Database logging and performance

Although database logging can be valuable from a business perspective, it can be expensive with regard to resource use and management. Here are some of the performance implications of database logging:

- The database log table can grow quickly and can increase the size of the database. The amount of growth depends on the amount of logged data that you decide to retain.
- When logging is turned on for a transaction type, each instance of that transaction type causes multiple records to be written to the Microsoft SQL Server transaction log file. Specifically, one record is written for the initial transaction, and one record logs the transaction in the database log table. Therefore, the transaction log file will grow more quickly and might require additional maintenance.
- Database logging can adversely affect long-running automated processes, such as inventory close, calculations for bills of materials (BOMs), master planning, and long-running data imports.
- When logging is turned on for a table, all set-based database operations are downgraded to row-based operations. For example, if you're logging inserts for a table, each insert is done as a row-based insert.

Here are some practices that Microsoft recommends:

- Create a plan for how long you will retain logged data, and how you will archive or delete data.
- Limit log entries, and help improve performance by selecting specific fields to log instead of whole tables.

**NOTE**

Only updates can be logged for individual fields.

- After you configure database logging, consider increasing the frequency of backups of the SQL Server transaction log.
Set up database logging

You can use the Logging database changes wizard to set up database logging. This wizard provides a flexible way to set up logging for tables or fields.

1. Go to System administration > Setup > Database log > Database log setup.
2. Select New to open the Logging database changes wizard.
3. Complete the wizard.

Clean up database logs

You can delete database logs as required. You can delete logs for specific tables, delete specific types of database logs, or delete logs based on the date and time when they were created.

1. Go to System administration > Inquiries > Database > Database log.
2. Select Clean up log.
3. Select the method that should be used to select the logs that are deleted. Enter the table ID that the logs refer to, the type of log, or the creation date and time.
4. Use the Database log cleanup tab to specify when the log cleanup task should be run.

Consistency check for database log triggers

In Platform update 34, functionality for a consistency check was added. The consistency check is run as part of the Database log wizard. It’s run after you select Finish or after you select Consistency check on the Database log setup page.

The consistency check will re-create any missing database log triggers. It will also drop any “orphaned” database log triggers that no corresponding configuration is found for. In this way, the consistency check quickly detects and fixes any inconsistencies between the current configuration and the database triggers that are used to implement the logging functionality.

1. Go to System administration > Inquiries > Database > Database log.
2. On the Database log page, select Consistency check.
With the release of Platform update 32, we have introduced the ability to build OData metadata cache when the Application Object Server (AOS) starts, instead of when the first OData request is made. This significantly decreases the response time for the first OData call after an AOS process restart.

This option is useful if your business process can't wait for the OData metadata cache to be built each time that the AOS process restarts. Follow these steps to turn on this feature.

1. Go to System administration > Setup > System parameters.
2. On the General Tab, select Build metadata cache when AOS starts, and then select Save.

**NOTE**

When you enable this functionality, the AOS should already be running and should have served one OData request. This means that the cache is already built. This new functionality will take effect during the next AOS restart.
The functionality for storing advanced certificates lets you define the type of certificate storage that is used in Finance and Operations apps.

The functionality provides two options for storing certificates: local storage and Microsoft Azure Key Vault storage. You can define the option that is used by setting the new *Use advanced certificate store* option on the General tab of the System parameters page (System administration > Setup > System parameters).

- **Local storage** – This storage option can be used with on-premises deployments and any kind of on-premises development environment. To use it, set the *Use advanced certificate store* option to **No**. This storage option is recommended for development environments that are used for development and validation purposes, where it's necessary to validate the certificate and work with it.

- **Azure Key Vault storage** – This storage option is required for cloud deployments, but it can also be used with on-premises deployed environments and any kind of on-premises development environment. To use it, set the *Use advanced certificate store* option to **Yes**. This storage option is the only option for a production environment in the Azure cloud.

Some setup is required before you can work with certificates that are stored in Key Vault. For information about the required settings, see the following Microsoft Knowledge Base (KB) article: 4040294 - Maintaining Azure Key Vault storage. After you set up the Key Vault storage, you should link to the certificates in Finance and Operations apps.

After the certificate is installed in Key Vault, it must be set up in the application.

1. Go to **System administration > Setup > Key Vault parameters**.
2. Select **New** to create a new instance.
3. Enter a name and description, and then, on the **General** FastTab, set the fields that are required for the integration with Key Vault storage:
   
   - **Key Vault URL** – Enter the default Key Vault URL if it isn't already defined by the secret reference.
   
   - **Key Vault client** – Enter the interactive client ID of the Azure Active Directory (Azure AD) application that is associated with the Key Vault storage for authentication.
   
   - **Key Vault secret key** – Enter the secret key that is associated with the Azure AD application that is used
for authentication with the Key Vault storage.

NOTE
If several Key Vault storages are used, you should set up a separate instance for each instance on the Key Vault parameters page.

4. On the Certificates FastTab, select Add to add your certificates. For each certificate, set the following fields:

- **Name**
- **Description**
- **Key Vault certificate secret** – Enter a secret reference to the certificate.

The format of a Key Vault certificate secret must resemble the following example:

```
vault://<KeyVaultName*>/<SecretName>/<SecretVersion*>
```

Attributes that are marked with an asterisk (*) are optional. However, the `<SecretName>` attribute is required.

In most cases, you can define a Key Vault secret key in the following format:

```
vault://<SecretName>
```

If the secret version isn’t defined in the Key Vault secret key, the system retrieves the active certificate that has the latest expiration date.

![Key Vault parameters](image)

NOTE
The Key Vault storage functionality has been extended so that it includes caching of certificates. The following configuration is recommended:

- Specify a secret version in the Key Vault certificate secret.
- After you upload a new version of the existing certificate to the Key Vault storage, update the `<SecretVersion>` attribute in the Key Vault certificate secret field.

Use the Validate function to verify that you’ve correctly defined the reference to the certificate, and that the certificate is valid.
In Microsoft Dynamics 365 Finance and Dynamics 365 Supply Chain Management, cleanup routines are available in various modules. This topic provides an overview of the routines that are currently available. The information is organized by module.

### System administration

<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>System administration &gt; Periodic tasks &gt; Notification clean up</td>
<td>This cleanup routine is used to periodically delete records from the EventInbox and EventInboxData tables. <strong>Recommendation:</strong> If you don't use alert functionality, turn off the alert from the batch job.</td>
</tr>
<tr>
<td>System administration &gt; Periodic tasks &gt; Batch job history clean-up</td>
<td>This regular version of the <strong>batch job history cleanup</strong> routine lets you quickly clean all history entries that are older than a specified number of days. Any entry that was created earlier will be deleted from the BatchJobHistory table, and also from linked tables that have related records (BatchHistory and BatchConstraintsHistory). This version has improved performance optimization, because it doesn't have to run any filtering.</td>
</tr>
<tr>
<td>System administration &gt; Periodic tasks &gt; Batch job history clean-up (custom)</td>
<td>This <strong>custom batch job history cleanup</strong> routine should be used only when specific entries must be deleted. You can clean up selected types of batch job history records, based on criteria such as status, job description, company, or user. You can add other criteria by using the <strong>Filter</strong> button.</td>
</tr>
<tr>
<td>System administration &gt; Inquiries &gt; Database &gt; Database Log &gt; Clean up log</td>
<td>This cleanup routine lets you delete database logs as you require. You can delete logs for specific tables, delete specific types of database logs, or delete logs based on the date and time when they were created. <strong>Note:</strong> Records that have been electronically signed can't be deleted from logs.</td>
</tr>
</tbody>
</table>

### Data management

**IMPORTANT**

These cleanup routines should be run only after the business has done detailed analysis and confirmed that the data is no longer required.

Always test each cleanup routine in a test environment before you run it in a production environment.
In the **Data management** workspace, select **Job history cleanup**.

This cleanup routine is available in Platform update 29 and later. To use it, you must turn on the **Execution history cleanup** feature in Feature management. In **Data management**, this routine must be used to schedule a periodic cleanup of the execution history. It replaces the earlier Staging cleanup routine, which is now obsolete (deprecated).

The following tables will be cleaned up:
- All staging tables
- DMFSTAGINGVALIDATIONLOG
- DMFSTAGINGEXECUTIONERRORS
- DMFSTAGINGLOGDETAIL
- DMFSTAGINGLOG
- DMFDEFINITIONGROUPEXECUTIONHISTORY
- DMFEXECUTION
- DMFDEFINITIONGROUPEXECUTION

In the **Data management** workspace, select the **Staging cleanup** tile.

This cleanup routine should no longer be used, because it’s obsolete. Instead, use the **Job history cleanup** routine.

### General ledger

<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
</table>
| **General ledger > Periodic tasks > Clean up ledger journals** | This cleanup routine deletes General ledger, Accounts receivable, and Accounts payable journals that have been posted. When you delete a posted ledger journal, all information that is related to the original transaction is removed.  

**Note:** You should delete this information only if you’re sure that you won’t have to reverse the ledger journal transactions. |

### Sales and marketing

<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Sales and marketing &gt; Periodic tasks &gt; Clean up &gt; Delete sales orders</strong></td>
<td>This cleanup routine deletes selected sales orders.</td>
</tr>
<tr>
<td><strong>Sales and marketing &gt; Periodic tasks &gt; Clean up &gt; Delete quotations</strong></td>
<td>This cleanup routine deletes selected quotations.</td>
</tr>
<tr>
<td><strong>Sales and marketing &gt; Periodic tasks &gt; Clean up &gt; Delete return orders</strong></td>
<td>This cleanup routine deletes selected return orders.</td>
</tr>
<tr>
<td><strong>Sales and marketing &gt; Periodic tasks &gt; Clean up &gt; Sales update history cleanup</strong></td>
<td>This cleanup routine deletes old update history transactions. All updates of confirmations, picking lists, packing slips, and invoices generate update history transactions. You can view these transactions on the <strong>History on update</strong> page.</td>
</tr>
</tbody>
</table>
### Procurement and sourcing

<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Procurement and sourcing &gt; Periodic tasks &gt; Clean up &gt; Purchase update history cleanup</td>
<td>This cleanup routine is used to delete all updates of confirmations, picking lists, product receipts, and invoices that generate update history transactions.</td>
</tr>
<tr>
<td>Procurement and sourcing &gt; Periodic tasks &gt; Clean up &gt; Delete requests for quotations</td>
<td>This cleanup routine is used to delete requests for quotation (RFQs) and RFQ replies. The corresponding RFQ journals aren't deleted but remain in the system.</td>
</tr>
<tr>
<td>Procurement and sourcing &gt; Periodic tasks &gt; Clean up &gt; Draft consignment replenishment order journal cleanup</td>
<td>This cleanup routine is used to clean up draft consignment replenishment order journals.</td>
</tr>
</tbody>
</table>

### Warehouse management

<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Warehouse management &gt; Periodic tasks &gt; Clean up &gt; Work creation history purge</td>
<td>This cleanup routine is used to delete work creation history records from the WHSWorkCreateHistory table. In the dialog box, you specify the number of days to keep the history.</td>
</tr>
<tr>
<td>Warehouse management &gt; Periodic tasks &gt; Clean up &gt; Containerization history purge</td>
<td>This cleanup routine is used to delete containerization history from the WHSContainerizationHistory table. In the dialog box, you specify the number of days to keep the history.</td>
</tr>
<tr>
<td>Warehouse management &gt; Periodic tasks &gt; Clean up &gt; Wave batch cleanup</td>
<td>This cleanup routine is used to clean up batch job history records that are related to the wave processing batch group.</td>
</tr>
<tr>
<td>Warehouse management &gt; Periodic tasks &gt; Clean up &gt; Cycle count plan cleanup</td>
<td>This cleanup routine is used to clean up batch job history records that are related to cycle count plan configurations.</td>
</tr>
<tr>
<td>Warehouse management &gt; Periodic tasks &gt; Clean up &gt; Mobile device activity log cleanup</td>
<td>This cleanup routine is used to delete mobile device activity log records from the WHSMobileDeviceActivityLog table. In the dialog box, you specify the number of days to keep the history.</td>
</tr>
<tr>
<td>Warehouse management &gt; Periodic tasks &gt; Clean up &gt; Work user session log cleanup</td>
<td>This cleanup routine is used to delete work user session records from the WHSWorkUserSessionLog table. In the dialog box, you specify the number of hours to keep records.</td>
</tr>
</tbody>
</table>

### Inventory management
<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inventory management &gt; Periodic tasks &gt; Clean up &gt; Calculation of location load</td>
<td>The WMSLocationLoad table is used to track the weight and volume of items and pallets. The Summation of load adjustments job can be run to reduce the number of records in the WMSLocationLoad table and help improve performance.</td>
</tr>
<tr>
<td>Inventory management &gt; Periodic tasks &gt; Clean up &gt; Inventory journals cleanup</td>
<td>This cleanup routine is used to delete posted inventory journals.</td>
</tr>
<tr>
<td>Inventory management &gt; Periodic tasks &gt; Clean up &gt; Inventory settlements cleanup</td>
<td>This cleanup routine is used to group closed inventory transactions or delete canceled inventory settlements. By cleaning up closed or deleted inventory settlements, you can help free up system resources. Don't group or delete inventory settlements that are too close to the current date or fiscal year, because part of the transaction information for the settlements will be lost. Closed inventory transactions can't be changed after they have been grouped, because the transaction information for the settlements will be lost. If canceled inventory settlements are deleted, they can't be reconciled with finance transactions.</td>
</tr>
<tr>
<td>Inventory management &gt; Periodic tasks &gt; Clean up &gt; Inventory dimensions cleanup</td>
<td>This cleanup routine is used to maintain the InventDim table. This batch process deletes all existing inventory dimensions that are defined but not used in the current company. All unused inventory dimensions are permanently deleted. No alert or database log is created during this process. This cleanup routine verifies if each InventDim record is being used in not only purchase order lines or sales order lines, but also inventory transactions or on-hand inventory records. If a reference exists to InventDim, it is checked. If it is not used, it will be deleted. If the same combination of dimensions is used later, Dynamics 365 Finance and Dynamics 365 Supply Chain Management will create a new InventDim record with a new InventDimId and use this instead.</td>
</tr>
</tbody>
</table>
| Inventory management > Periodic tasks > Clean up > Dimension inconsistency cleanup | This cleanup routine is used to resolve dimension inconsistencies on inventory transactions that have been financially updated and closed. Inconsistencies might be introduced if the multisite functionality was activated during or before the upgrade process. Use this routine only to clean up the transactions that were closed before the multisite functionality was activated.  

**Note:** Don't use this routine periodically. |
<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inventory management &gt; Periodic tasks &gt; Clean up &gt; On-hand entries cleanup</td>
<td>This cleanup routine is used to delete closed and unused entries for on-hand inventory that is assigned to one or more tracking dimensions. Closed transactions contain a value of 0 (zero) for all quantities and cost values, and they are marked as closed. By deleting these transactions, you can help improve the performance of queries for on-hand inventory. Transactions won't be deleted for on-hand inventory that isn't assigned to tracking dimensions.</td>
</tr>
<tr>
<td>Inventory management &gt; Periodic tasks &gt; Clean up &gt; Warehouse management on-hand entries cleanup</td>
<td>This cleanup routine deletes records in the InventSum and WHSInventReserve tables. These tables are used to store on-hand information for items that are enabled for warehouse management processing (that is, WHS items). By cleaning up these records, you can significantly improve the on-hand calculations.</td>
</tr>
<tr>
<td>PATH</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>Inventory management &gt; Periodic tasks &gt; Clean up &gt; On-hand entries aggregation by financial dimensions</td>
<td>Use This cleanup routine as a tool to aggregate InventSum rows that have 0 (zero) quantities. This routine basically extends the previously mentioned routine by also cleaning up records where the <strong>Closed</strong> field is set to <strong>True</strong>. Basically, this routine is needed to handle scenarios where there are no more quantities in the InventSum table for a combination of inventory dimensions, but there is still a value. Although these values will disappear in some cases, the current design occasionally allows values to remain. For example, if you use batch numbers, each batch number (and the combined site, warehouse, and so on) creates a new record in the InventSum table. When the batch number is sold, you will see that quantity fields are set to 0 (zero). In most cases, the <strong>Financial cost amount</strong> and <strong>Physical cost amount</strong> fields are also set to 0 (zero). However, in standard cost revaluation and other scenarios, the field might still show some amount. This behavior is valid, and it reflects the way that Finance and Supply Chain Management handle the costs at the financial inventory level (for example, the site level). In Finance and Supply Chain Management, inventory value is determined by records in the InventSum table. In some cases, when inventory values in the past are reported, it’s determined by inventory transactions (the InventTrans table). Therefore, in the previously described scenario, when you run inventory value reports, Finance and Supply Chain Management initially look at the InventSum table, aggregate all records to the site level, and report the value for the item per site. The data from the individual records at batch number level are never used. Therefore, this routine goes through all InventSum records, finds the records where there is no more quantity (that is, <strong>No open quantities</strong> field is set to <strong>True</strong>). Because there is no reason to keep these records, Finance and Supply Chain Management find the InventSum record for the same item that has the same site, they copy the values from the batch number level to the site level, and they delete the record. Then, when you run inventory value reports, Finance and Supply Chain Management still find the same correct values. Therefore, this routine reduces number of InventSum records, significantly in some cases, and can have a positive impact on the performance of any function that queries that table.</td>
</tr>
<tr>
<td>Inventory management &gt; Periodic tasks &gt; Clean up &gt; Cost calculation details</td>
<td>This cleanup routine is used to clean up cost calculation details.</td>
</tr>
</tbody>
</table>

**Production control**
<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Production control &gt; Periodic tasks &gt; Clean up &gt; Production</td>
<td>This cleanup routine is used to delete unused journals.</td>
</tr>
<tr>
<td>journals cleanup</td>
<td></td>
</tr>
<tr>
<td>Production control &gt; Periodic tasks &gt; Clean up &gt; Production</td>
<td>This cleanup routine is used to delete production orders that are ended.</td>
</tr>
<tr>
<td>orders cleanup</td>
<td></td>
</tr>
<tr>
<td>Production control &gt; Periodic tasks &gt; Clean up &gt; Clean up</td>
<td>We recommend that you periodically clean up registrations. This cleanup routine deletes only data that has been processed.</td>
</tr>
<tr>
<td>registrations</td>
<td><strong>Note:</strong> Make sure that you don't delete registrations that might be required later for documentation purposes.</td>
</tr>
<tr>
<td>Production control &gt; Periodic tasks &gt; Clean up &gt; Archive</td>
<td>This cleanup routine is used to remove future registrations from the raw registrations table.</td>
</tr>
<tr>
<td>future registrations</td>
<td></td>
</tr>
</tbody>
</table>

**Master planning**

<table>
<thead>
<tr>
<th>PATH</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Master planning &gt; Master planning &gt; Maintain plans &gt; Plan</td>
<td>Usually, this cleanup is done automatically. However, automatic cleanup sometimes malfunctions, and orphan data remains in the system. This orphan data slows down queries and causes the database size to grow. We recommend that you do a preventive run one time per month, when master resource planning (MRP) isn't running.</td>
</tr>
<tr>
<td>version cleanup</td>
<td></td>

Upgrades, updates, and hotfixes can include moving to new product versions, code migration and upgrade, moving to an update, or deploying a hotfix.

The processes for each type of upgrade are similar, but different enough that we think that you should review the topics for a specific task before you begin.

Upgrade from Microsoft Dynamics AX 2012 to Finance and Operations

To get started, review the following topics:

- Upgrade from AX 2012 to Finance and Operations
- Prepare to migrate code to Finance and Operations

Migration from Microsoft Dynamics AX 2009 to Finance and Operations

This Tech Talk video provides an introduction to migration from AX 2009 to Finance and Operations: Dynamics 365 for Operations – Tech Talk: Migration tools.

Upgrade from a previous version of Finance and Operations

The steps for applying updates and upgrading differ between cloud and on-premises implementations.

Cloud

If you are upgrading a cloud version of Finance and Operations, review the following topics:

- Process for moving to the latest update of Finance and Operations
- Apply the latest platform update to environments
- Download updates from Lifecycle Services (LCS)

On-premises

If you are applying updates to an on-premises version of Finance and Operations, review the following topic:

- Apply updates to on-premises deployments
- Redeploy on-premises environments

Hotfixes

- Download updates from Lifecycle Services (LCS)
- Apply updates to cloud environments
- Install metadata hotfixes in development environments
- Patch SQL Server Reporting Services (SSRS) in one-box environments
- Update the Visual Studio development tools

This Tech Talk video provides an introduction servicing (applying code updates, requesting sandbox database

For more information, see:

- Refresh database
- Set up technical support for Finance and Operations apps
Upgrade from AX 2012 to Finance and Operations
11/24/2021 • 13 minutes to read • Edit Online

IMPORTANT
Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

Finance and Operations apps provide an upgrade path that customers who currently run Microsoft Dynamics AX 2012 can use to move their data and code to Finance and Operations apps. Currently, upgrades from Dynamics AX 2012 R3 and AX 2012 R2 are supported. The upgrade process is built on the following elements:

- Tools to help you bring forward existing custom application code from AX 2012.
- A data upgrade process that you can use to bring your database forward. Therefore, you can upgrade your full transactional history.

IMPORTANT
Dynamics AX 2012 implementations that are running some deprecated features cannot currently be upgraded. For example, upgrade is not possible from systems that are using either virtual companies or data partitions. If you aren’t sure whether your system can be upgraded, run the Upgrade analyzer tool.

Start your cloud migration journey with a no-charge, no-obligation migration assessment though the Dynamics 365 Migration Program.

Overview
The overall upgrade process can be visualized as three overarching phases: Analyze, Execute, and Validate.

The following diagram shows the end-to-end upgrade process, and the activities that we consider part of each phase.

To learn the most important elements and best practices for successfully upgrading your Dynamics AX 2012 solution to Finance and Operations apps, see Upgrade Dynamics AX 2012 to Finance and Operations apps.

Analyze
The activities in the Analyze phase help you estimate the effort that is required for the upgrade. They also help
you prepare a project plan. These activities can be done before you buy Finance and Operations. They will help you make an informed purchase decision by providing a data point about the effort and resources that you will require.

**Sign up for a preview subscription**
To sign up for a preview subscription, see Sign up for preview subscriptions.

**Append the upgrade methodology**
In your new LCS project, append the project methodology with Upgrade AX 2012 to Dynamics 365 for Finance and Operations. This methodology is specifically for AX 2012 customers who are upgrading. It describes the three phases in detail and provides links to all the supporting documentation about the process.

**Run the upgrade analyzer**
The upgrade analyzer tool runs against your AX 2012 environment and identifies tasks that you should do to prepare the AX 2012 environment, to help make the upgrade experience smoother and less expensive:

- **Data cleanup** – This process helps you identify data that you can remove without causing loss of functionality. The tool identifies various types of data that you can reduce by running a cleanup process. For each type of data, an explanation is given about the impact of the cleanup. You then decide whether to run the cleanup process. Part of the cost of your subscription is based on database size. Therefore, by reducing the size, you reduce that component of the subscription cost and also help reduce the time that is required for the upgrade go-live process. A smaller database helps guarantee a faster upgrade.

- **SQL configuration** – This process reviews the SQL configuration and recommends optimizations. By making sure that SQL performs optimally, this process helps reduce the time that is required for the upgrade go-live process.

- **Deprecated features** – This process identifies features that you're currently using, but that aren't available in Finance and Operations. Therefore, the process helps you discover gaps in functionality early. It also provides suggestions for alternatives.

Additionally, as part of this step, you must install a pre-upgrade checklist in your AX 2012 environment. You can use this checklist to enter data that will be required for the upgrade procedure. For example, in one pre-upgrade checklist task, you provide the Microsoft Azure Active Directory (Azure AD) sign-in information for each current AX 2012 user, so that each user will be able to sign in to Finance and Operations.

- If upgrading from AX 2012 R3, install KB 4035163.
- If upgrading from AX 2012 R2, install KB 4048614.

The output of the upgrade analyzer tool becomes the workstream in the upgrade project plan for your AX 2012 system administrators. For more information, see Upgrade from AX 2012 - Plan by using the Upgrade analyzer tool.

**Run the Code upgrade estimation tools**
This step takes your code from AX 2012, converts it to the new format, and provides feedback about conflicts that a developer must resolve later. This step forms the basis for the estimate of the cost of your code upgrade.

To complete this step, you must export your code from AX 2012 as a model store export and upload it to the LCS Code upgrade tool. The Code upgrade tool will produce an upgraded version of your code and a report about the remaining conflicts that must be resolved. Your developer can then review both the upgraded code and the report to determine the effort that will be required in order to upgrade your code base.

The output of this step represents the workstream in the upgrade project plan for your Microsoft Dynamics AX developers.

For more information, see Upgrade from AX 2012 - Estimate effort by using the Code upgrade service.

**Deploy a demo environment**
Demo environments are default environments that contain demonstration data (not your own data) and standard code (no customizations). We recommend that you deploy a demo environment to evaluate new features, and to perform a basic fit gap analysis of standard processes that are used in AX 2012 but that might have changed in Finance and Operations. You can either deploy these demo environments in Azure or downloaded them as a virtual machine (VM) that you run on your own hardware. If you deploy them in Azure, you must provide your Azure subscription, because you’re still using a public preview project and haven’t yet purchased a subscription.

The output of this step represents the workstream in the upgrade project plan for your functional users or business users.

For more information, see Upgrade from AX 2012 - Deploy a demo environment for analysis

Create a project plan

A template for a project plan is provided in the upgrade methodology. In this step, the output from the previous steps of the Analyze phase is used to fill the project plan for the upgrade project. The project plan will also contain all testing details: data upgrade testing, cutover testing (mock cutover), the functional test pass iterations, and details about the various resource assignments for those tasks.

At this stage, the project plan provides a data point that can help you understand the time and cost of an upgrade.

Execute

During the Execute phase, you work through the tasks that you planned during the Analyze phase. To move to the Execute phase, you must purchase Finance and Operations apps, and you must have available resources that can work on the upgrade.

Switch to the LCS implementation project

The public preview project that you used for the Analyze phase has served its purpose. You can now discard it. For the remaining steps, you require only the project plan that you created in the final step of the Analyze phase.

When you purchase a Finance and Operations subscription, you will receive details about how to sign up for a new LCS project. This project is known as an implementation project and will be the new permanent LCS project for your tenant, for as long as you have that subscription. This project differs from the public preview project in that it's managed by Microsoft. Therefore, this project has these characteristics:

- This project supports deployment of Sandbox and Production type environments.
- The Sandbox and Production type environments are maintained and patched by the Microsoft team, not your staff.
- All DevTest or Demo environments must still be deployed on an Azure subscription. It is recommended to redeploy these environments from your LCS Implementation project so that they are all contained in the same project as your sandbox and production environments.

Identify the project as an AX 2012 upgrade

When you first sign in to your LCS implementation project, you're guided through the Project Onboarding wizard. You can always visit the Project Onboarding wizard later using the navigation menu next to Project Settings in your project.

In the Project Onboarding wizard, in the Project Scope section, you can use the Legacy System field to identify the project as an AX 2012 upgrade. It’s crucial that you identify the project in this way.

Perform the AX 2012 preparation tasks

Complete the tasks that the upgrade analyzer tool discovered, and that are documented in your upgrade project plan. Your Microsoft Dynamics AX system administrator and database administrator (DBA) must complete these
Perform code upgrade
Complete the tasks that were planned during the code upgrade estimation step of the Analyze phase. Your developers must run these tasks.

From this point onward, code changes in AX 2012 should be frozen. Only emergency code changes should be allowed in AX 2012. If a change is made, it must be ported manually to the new code base.

Develop new code
Complete the tasks from the fit gap analysis that was performed during the “Deploy a demo environment” step of the Analyze phase. These tasks will probably be a mixture of functional tasks that define the configuration and development tasks for customizations that are related to new features that are being taken up.

Data upgrade (development environment)
After your code upgrade tasks are completed, you can upgrade your database for the first time. This first upgrade occurs in a development environment, so that you can more easily remediate or debug any issues that are found at this stage. In a development environment, an issue can be debugged immediately, code can be adjusted, and the upgrade can be rerun within minutes. Sandbox environments don’t offer this agility, and a minimum of several hours will be required in order to debug and remediate issues, update code, deploy the updated code, and rerun the upgrade.

The following illustration shows the process. Just back up the AX 2012 database, upload it to Azure, restore it to the Finance and Operations environment, and then run the data upgrade.

Data upgrade is done through a special type of deployable package. The same mechanism is used to deploy new code from one environment to another environment.

The underlying framework that is used to convert the data in the database during this process is largely the same as the upgrade framework in AX 2012 that is based on X++ batch jobs that run ReleaseUpdatexxx classes.

For details, see Upgrade from AX 2012 - Data upgrade in development environments.

NOTE
If you are using Commerce functionality and in-store components as part of the AX 2012 R3 upgrade, we recommend that you review the Dynamics 365 Commerce Phased rollout (N-1) installation, configuration, and cutover guide. For development environments, the user will need to initialize retail parameters, reinitialize the CDX schedule, and then after applying the data upgrade package, the latest quality updates and channel extensions will need to be applied to the environment.

Data upgrade (sandbox environments)
When data upgrade in a development environment completes, you must perform data upgrade in a sandbox environment. For more information about sandbox deployment, see Self-service deployment overview. The sandbox environment is the environment where business users and functional team members can test business processes by using the upgraded AX 2012 data and code.

The following illustration shows the process for running data upgrade in a sandbox environment. The difference
here is that the **AX 2012 Database Upgrade Toolkit for Dynamics 365** is used instead of a traditional SQL backup. This toolkit is required to move your AX 2012 data to Azure SQL Database (using SQL Transaction Replication) as well as to run the data upgrade. In this case, your source is AX 2012 database and target is the Finance and Operations sandbox environment.

For more information, see [Upgrade from AX 2012 - Data upgrade in self-service environments](#).

---

**NOTE**

If you are using Commerce functionality and in-store components as part of the AX 2012 R3 upgrade, we recommend that you review the Dynamics 365 Commerce Phased rollout (N-1) installation, configuration, and cutover guide. For sandbox and development environments, the user will need to initialize retail parameters, reinitialize the CDX schedule, and then reinitialize the CSU after data upgrade. For more information about reinitializing the CSU, see [Initialize Commerce Scale Unit (cloud)](#).

---

**Validate**

When you enter the Validate phase, you will have available environments that include your upgraded custom code and your upgraded data. This phase describes the process of validating and testing that the upgraded environment works as desired. It also describes the process of preparing for go-live.

**Perform cutover testing and create a cutover plan**

The term **cutover** is used here to describe the final process of putting the new system live. This process consists of the tasks that occur after AX 2012 is turned off and before Finance and Operations is turned on.

The goal of the testing, or **mock cutover** is to practice the cutover process. In this way, you can help guarantee that everyone who is involved in the actual cutover to go-live will have a smooth experience.

There are two main workstreams:

- **Technical workstream** – This workstream is the process of running the data upgrade. Your business will enforce a limit on the amount of downtime that is allowed. During this downtime, neither product database will be available. The technical workstream might have to performance-tune its data upgrade procedure to meet the business’s downtime limit.

- **Functional workstream** – After data upgrade, several configuration tasks will be required in the Finance and Operations environment. All these tasks must be documented and quantified, and a resource must be assigned to them, because they must fit together with the technical tasks within the business’s downtime limit.

For additional details, see:

- [Upgrade from AX 2012 - Post-upgrade tasks](#)
- [Upgrade from AX 2012 - Cutover testing (Mock cutover)](#)

**Functional test pass**

Complete a full functional test pass of all business processes. This test pass will be an extensive retest of all business processes that involve Finance and Operations. These business processes include both old processes that were brought forward from AX 2012 and new processes that involve new features that were taken up for the first time in Finance and Operations.

Depending on code quality, issue remediation and retesting might require several iterations of the functional test pass. When an issue is fixed, be sure to retest all processes that are involved, to help guarantee that the
downstream or upstream process isn't affected by the change.

For details, see Upgrade from AX 2012 - Functional test passes.

**Pre-go-live checklist**

The pre-go-live checklist is a recommended procedure that can help reduce the chance of errors during the final cutover to go-live. One week before go-live is due, stop configuration changes in AX 2012 (that is, under <module>\Setup). This restriction on configuration changes is merely procedural. The Microsoft Dynamics AX system administrators just agree to put changes of this type on hold at this point.

We recommend that you also freeze code changes in the Finance and Operations code base. No further changes should be allowed unless they have been evaluated and have been shown not to block go-live.

After the configuration restriction and code freeze are in place, data upgrade should be run for the last time before cutover. In this way, you can make sure that everything still works as expected.

For more information, see Validate: Prepare for go live.

**Go live**

After you have successfully completed upgrade testing in a Standard or Premier Acceptance Test environment (Sandbox Tier 2 or higher), and you have also completed a successful test cutover, the moment has arrived to upgrade your production environment and go live.

*Cutover* is the term that we use for the final process of getting a new system live. This cutover process consists of the tasks that occur after Dynamics AX 2012 is turned off but before Finance and Operations is turned on.

For details, see Upgrade from AX 2012 - Cutover process (Go live).

**Supported upgrade paths**

Upgrade to the cloud version of Finance and Operations apps is supported from AX 2012 R2 and AX 2012 R3.

Upgrade from Dynamics AX 2012 RTM isn't currently supported. Upgrade to the on-premises version is supported, as documented in Data upgrade process for AX 2012 to Dynamics 365 Finance + Operations (on-premises).
This topic explains how to use the Upgrade analyzer tool to plan your upgrade from Microsoft Dynamics AX 2012. This tool is run against an AX 2012 environment and identifies data that you should clean up in AX 2012 to help reduce the subscription cost for Finance and Operations. The tool also suggests SQL configuration optimizations that can help speed up the upgrade processes. Additionally, the tool warns you if any features that you use in AX 2012 are obsolete in the current version. Therefore, you can plan ways to replace or work around those features.

Upgrade analyzer gathers data from your AX 2012 environment as part of the regular System diagnostic service in Dynamics Lifecycle Services (LCS). For an overview of the System diagnostic service, and for information about how data is collected and pushed back into the cloud so that you can consume it through LCS, see System diagnostics in Lifecycle Services (LCS).

You can view the results of the System diagnostic service in a Microsoft Power BI report in LCS. The report presents a list of tasks that you should complete in the AX 2012 environment.

To access the Upgrade analyzer report, go to https://diag.lcs.dynamics.com/UpgradeAnalysisReport/Report/"ProjectID" (Replace "ProjectID" with your current project ID, which is an integer that can be found in the URL of your current LCS project).

The following illustration shows an overview of the procedure for using Upgrade analyzer.

If you already use the System diagnostic service in your AX 2012 environment, you must configure a new instance of the service on a machine that differs from the existing machine.

For information about how to configure the System diagnostic service in your AX 2012 environment, see Install and run System diagnostics.

Within a few minutes after you configure the System diagnostic service, the AX 2012 environment will appear in your LCS project.
This topic explains how to use the Code upgrade service in Microsoft Dynamics Lifecycle Services (LCS) to help estimate the tasks and effort that are required in order to upgrade a code base from Microsoft Dynamics AX 2012 Finance and Operations.

The Code upgrade service converts an export of your AX 2012 model store to the correct format. However, the new version of your code won’t be fully functional until a developer resolves any issues that the service identifies but can’t resolve itself.

The Code upgrade service performs these actions:

- Directly resolve some types of conflict issues.
- For other issues, log Microsoft Azure DevOps tasks.
- Create a version of your code in the correct format, and check the new version into a new branch of your Azure DevOps project.

In the Analyze phase, we use the report to help estimate the effort that is required in order to complete code conversion activities.

The following illustration shows an overview of the process for configuring the Code upgrade service.

For information about how to configure the Code upgrade service, see Configure the code upgrade service in Lifecycle Services (LCS).

The output of the Code upgrade service is designed to be consumed by a developer. This output will help the developer estimate the effort that is required in order to complete the code upgrade tasks. To form an estimate, the developer must review the tasks that the service generates in Azure DevOps and the new version of the code that the service generates.
This topic explains why and how you should deploy a demo environment during the Analyze phase of your project for upgrading from Microsoft Dynamics AX 2012 to Finance and Operations.

By deploying a demo Finance and Operations environment, you gain hands-on experience with the program and can explore new features that you might be interested in. You also have an opportunity to validate differences in the program for your business processes, so that you can identify potential gaps or confirm that no gaps exist. At this stage in your upgrade project, your data and code won’t be available in the environment. Therefore, you will have limited ability to validate that everything conforms to your business process. However, this step is the first step in that work stream.

If you haven’t yet purchased licenses, and you’re using a free trial, you can follow the steps in Deploy a demo environment to deploy a demo environment to a Microsoft Azure subscription that you bring yourself.

If you’ve already purchased licenses, you received a link to configure a special type of project in Microsoft Dynamics Lifecycle Services (LCS): an implementation project. The implementation project will let you deploy a dev/test environment and a sandbox environment. For more information about this type of environment deployment, see Upgrade from AX 2012 - Data upgrade in sandbox environments.
This is an exciting moment in the upgrade project. The output of this task provides the first upgraded dataset from Microsoft Dynamics AX 2012 to the latest Finance and Operations development environment.

Before you run this process in a shared sandbox environment, we recommend that you run it in a development environment. There are two reasons for this approach:

- It provides local data that developers can write and test their custom data upgrade scripts against.
- It helps reduce the overall time that is spent on iterations of the data upgrade process. In a development environment, an issue can be debugged immediately, code can be adjusted, and the upgrade can be rerun within minutes. However, larger sandbox environments don't allow for this level of agility. In those environments, a minimum of several hours will be required to debug and remediate issues, update code, deploy the updated code, and rerun the upgrade.

We strongly recommend that you run the Upgrade analyzer and respond to the issues it identifies before running data upgrade - this will help ensure that your data upgrade is quicker and easier.

End-to-end data upgrade process

Back up your AX 2012 database
To back up your AX 2012 database, use the standard Microsoft SQL Server process to produce a BAK file. If you use the compression option when you create the backup, the file size will be smaller, and less time is required in order upload it to and download it from Microsoft Azure Storage.

Upload the backup to Azure Storage
If your developer environment is hosted as a VM locally or in Azure, you will need to transfer the 2012 database backup to it. With a local VM you may be able to transfer the file directly across the network (if you have configured the virtual network to allow that) but for an Azure hosted VM we recommend that you upload your backup to Azure Storage (using your own secure file transfer service or SFTP is also a valid option). You would need to provide your own Azure storage account for this. There are free tools to help you to move files between Azure storage, from a command line you can use Azcopy, or for a GUI experience you can use Microsoft Azure storage explorer. Use one of these tools to first upload the backup from your on-premises environment to Azure storage and then on your download it on your development environment.

Download and restore the backup to the customer-managed development environment
When you restore the backup to the new development environment, don’t overwrite the existing AXDB database. Instead, restore the AX 2012 database next to the original databases. You might also consider using drive D for the data and log files, to help improve performance. However, there is a potential downside to using drive D. If the underlying virtual machine (VM) is deallocated in Azure and then reallocated, drive D will be wiped. In practice, this scenario rarely occurs. Therefore, you might find that the risk is acceptable. To learn more about how to use drive D, see [Understanding the temporary drive on Windows Azure Virtual Machines](#).

To speed up the database restore process, you can change the SQL Server service account to `axlocaladmin`. The restore process can then use instant file initialization. For more information, see [Database Instant File Initialization](#).

After the database is restored, stop the following services:

- World wide web publishing service
- Dynamics 365 for Finance and Operations Batch Management service
- Management Reporter 2012 Process service
- Microsoft Dynamics Lifecycle Services Diagnostic Service
- Data Import / Export service

Next, rename the original AXDB database `AXDB_orig`. This database might be useful as reference later, when you develop code.

```
ALTER DATABASE AXDB SET SINGLE_USER WITH ROLLBACK IMMEDIATE
GO
ALTER DATABASE AXDB MODIFY NAME = AXDB_Orig
GO
ALTER DATABASE AXDB_Orig SET MULTI_USER
GO
```

Finally, rename the newly restored AX 2012 database `AXDB`.

**Run the data upgrade deployable package**

To get the latest data upgrade deployable package for a target environment that is running the latest update, download the latest binary updates from Microsoft Dynamics Lifecycle Services (LCS) Shared asset library.

1. Sign in to [LCS](#).
2. Select the `Shared asset library` tile.
3. In the `Shared asset` library, under `Select asset type`, select `Software deployable package`.
4. In the list of deployable package files, find the data upgrade package that corresponds to your upgrade. For example, if you're upgrading from AX 2012, the package name starts with AX2012DataUpgrade. Select the package that corresponds to the release you are upgrading to. For example: AX2012DataUpgrade-July2017.

For more information, see [Upgrade data in development or demo environments](#).

**Troubleshooting data upgrade script errors**

There are options that let you resume the data upgrade where it last stopped. You can also record any data upgrade script errors with call stacks to a table in the database. For development scenarios, you can skip failed scripts and continue to run the upgrade.
Recommendation for the first data upgrade run

When you run the data upgrade against your dataset for the first time, and especially when there many customizations or many custom data upgrade scripts, you might find the feature to skip failed scripts useful. By using this feature, you gain visibility into as many errors as possible in one run. Otherwise, only one critical issue is discovered per run. Be aware that, because dependencies exist between scripts, you might receive errors in related child scripts if you skip the parent script. These errors occur only because the parent wasn’t run correctly. They will be resolved when the issue in the parent script is resolved.

For more details, see the main data upgrade topic.
Upgrade from AX 2012 - Pre-upgrade checklist for data upgrade

This topic describes each task in the Microsoft Dynamics AX 2012 checklist that is associated with data upgrade to Finance and Operations.

Installation

Use the pre-upgrade checklist to enter data that will be required for the upgrade procedure.

- If upgrading from AX 2012 R3, install KB 4035163
- If upgrading from AX 2012 R2, install KB 4048614

Prepare model metadata

During data upgrade, one goal is to maintain element IDs between the existing AX 2012 environment and the upgraded Finance and Operations environment. To accomplish this goal, you must bring a copy of the element IDs from the AX 2012 environment into the Finance and Operations environment. AX 2012 stores element IDs in a table that is named ModelElement. This table is in the model database, which is a separate database from the AX 2012 business data database. During an upgrade to Finance and Operations, you must copy the AX 2012 database to Microsoft Azure. This process can be time consuming.

To avoid copying the whole model database to Azure SQL Database, use the following procedure to replicate the ModelElement table in the business data database. Later, during data upgrade runs, the database synchronization process will retrieve the required information from this replicated table and make sure that element IDs are maintained in the upgraded Finance and Operations environment.

1. In the Finance and Operations data upgrade checklist, click Prepare model metadata.
2. When you’re prompted, click Yes.
3. Wait for the copy process to be completed.

If the process is successful, the task is marked as completed.

Prepare security role metadata

Another goal during data upgrade is to preserve security role assignments. This task resembles the previous "Prepare model metadata" task. Security role information that is stored in the AX 2012 model database must be copied to the AX 2012 business data database, so that the information is preserved in the Finance and Operations environment after upgrade. During data upgrade runs, the same security role will be restored in the upgraded Finance and Operations environment.

1. In the Finance and Operations data upgrade checklist, click Prepare security role metadata.
2. When you’re prompted, click Yes.
3. Wait for the copy process to be completed.

If the process is successful, the task is marked as completed.

**Set up user mapping**

In AX 2012, users are authenticated against an on-premises Active Directory server. However, in Finance and Operations, users are authenticated against Azure Active Directory (Azure AD). This task provides a form where you can map existing AX 2012 users to equivalent Azure AD users. The AX 2012 users will then be able to access Finance and Operations.

1. In the Finance and Operations data upgrade checklist, click **Set up user mapping**.

2. The **User info email mapping** form appears. Follow one of these steps to fill in the grid:
   - Import users from AX 2012, and then manually fill in the Azure AD email address:
     a. Click **Import from AX**. The grid is filled with existing users.
     b. For each user, enter the corresponding Azure AD email address, as shown in the following illustration.

   ![User info email mapping](image)

   - Import users from a file. This option is faster. We recommend that you use this option when many users must be updated.
     a. In a comma-separated values (CSV) file, create the mapping between AX 2012 users and Azure AD email addresses. Your IT department can export a similar mapping from your on-premises Active Directory Domain Services (AD DS). The file should have two columns: **UserId** and **EmailAddress**.

     **NOTE**

     The first row in the file is treated as a header row and will be ignored during the import.

     b. After the file is ready, click **Import from file**, browse to the file, and import it.

     The grid should be filled with the mappings that you specified in the file.

If the imported file contains an entry that isn’t valid, an error file is generated.

**Validate baseline version**

Run this task to validate that the current version can be upgraded.

- In the Finance and Operations data upgrade checklist, click **Validate baseline version**.

If the baseline version is one of the supported baseline versions, the task is marked as completed.

**Archive retail salt data**

This task is used to migrate the registry key that RetailSaltUtility uses. This tool is used for some deployments where the customer wants to inject a specific random value into the hash that is used to authenticate channel
users.

- In the Finance and Operations data upgrade checklist, click **Archive retail salt data**.

If the process is successful, the task is marked as completed.
Upgrade from AX 2012 - SQL Transactional Replication

11/24/2021 • 8 minutes to read • Edit Online

**IMPORTANT**
Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

This topic shows how to upgrade a large Microsoft Dynamics AX 2012 database to Finance and Operations apps. This process uses SQL Transactional Replication to bring the schema and data from the AX 2012 on-premises database to the sandbox environment.

We strongly recommend that you run the data upgrade process in a development environment before you run it in a shared sandbox environment. This approach will help reduce the overall time that is required for a successful data upgrade. For more information, see Upgrade from AX 2012 - Pre-upgrade checklist for data upgrade.

**Replication setup**

Replication is a set of technologies for copying and distributing data and database objects from one database to another, and then synchronizing between the databases to maintain consistency. This migration and copying happens with the source system online, which means there is no need for Finance and Operations service downtime during the replication process. The Online Database Migration Toolkit uses transactional replication. This is typically used in server-to-server scenarios that require high-throughput to improve scalability and availability.

The Online Database Migration Toolkit can be downloaded from Lifecycle Services (LCS) in Shared asset Library > Model.

**Prerequisites**

The following prerequisites are needed for the Online Database Migration Toolkit.

- The source SQL Server should have the replication feature installed and enabled. To check whether replication is enabled, execute the following SQL script:

```sql
-- If @installed is 0, replication must be added to the SQL Server installation.
USE master;
GO
DECLARE @installed int;
EXEC @installed = sys.sp_MS_replication_installed;
SELECT @installed;
```

If the replication components are not installed, follow the steps in Install SQL Server replication.

- SQL Agent should be running in the source database server.

- SA Authentication: A user should have DB_Owner privilege in the source database and the target database. In the source database, the user should have access to masterDb and sourceDb.
- Update the target firewall by allow-listing the source IP. This can be done via LCS. This only allows for 8 hours of access. After allow-listing, you need to execute the following stored procedure in the target database to have more than 8 hours of access.

```sql
-- Create database-level firewall setting for IP a.b.c.d
EXECUTE sp_set_database_firewall_rule N'AX 2012 Upgrade', 'a.b.c.d', 'a.b.c.d';
```

- To optimize the replication latency/performance, the following are fine-tuned distributors parameters that can be updated in the `params.xml`.
  - MaxBcpThreads
  - NumberOfPublishers
  - Distributor database paths

- Stop the AOS service in the target environment, so that the target database will get replicated more efficiently. Running the AOS in the target may cause slowdown in the replication process. This may cause schema lock or deadlock in the replication process.

- When setting up Distributor: The script creates a database in the source server. Be sure you have enough space. The recommended is minimum to have the size of the source database. In `params.xml`, specify the distributor database path so that the database can be created in the specified path.

- Update `params.xml`

```xml
<?xml version="1.0" encoding="UTF-8"?>
<! -- Database replication parameters for an AX 2012 to Dynamics 365 upgrade -->
<Config>
  <!-- Edit the properties in this section for your source AX 2012 database -->
  <SourceDatabase>
    <Server>SQLSERVERNAME\SQLINSTANCE</Server>
    <Database>MicrosoftDynamicsAX</Database>
    <UserName>ReplicationUser</UserName>
    <Password>********************</Password>
  </SourceDatabase>
  <!-- Edit the properties in this section for your target Dynamics 365 database -->
  <TargetDatabase>
    <Server>dbmigration.database.windows.net</Server>
    <Database>dbms-prod</Database>
    <UserName>axdbadmin</UserName>
    <Password>*******************</Password>
  </TargetDatabase>
  <!-- Edit the properties in this section for your local SQL replication settings -->
  <SQLReplicationSettings>
    <!-- Ensure that you have enough space in the drive/path -->
    <SnapshotWorkingDir>D:\SQLServer\Snapshot</SnapshotWorkingDir>
    <DistributorDBDataFolder>D:\SQLServer\Data</DistributorDBDataFolder>
    <DistributorLogFolder>D:\SQLServer\Data</DistributorLogFolder>
    <!-- Based on the number of cores, you can set this, but the max this value can be is 8. This value should be between 4 to 8 -->
    <MaxBcpThreads>4</MaxBcpThreads>
    <!-- To increase the performance of the replication. This value should be between one and three. This value will be used to create the number of publishers for tables with primary keys. -->
    <NumberOfPublishers>2</NumberOfPublishers>
    <!-- Ignore DB objects xml file. The database objects listed in these files will be not be replicated. -->
    <IgnoreTablesList>Data\ignoretables.xml</IgnoreTablesList>
    <IgnoreFunctionsList>Data\ignorefunctions.xml</IgnoreFunctionsList>
  </SQLReplicationSettings>
</Config>
```

- XML Schema: To ignore selected tables, views, and functions during replication, add this information.
Configuring replication

The **SQLTransactionalReplication** folder has all the Windows PowerShell scripts that are required to configure the SQL transactional replication. These scripts should be executed using the following sequence. Be sure to wait for the process to finish.

1. **Replication_01_DataBaseCleanup.ps1** - Will empty the target database.

2. **Replication_02_Distributor.ps1** - Upon completion, the distributor database will get created in the source database server under the system database.

3. **Replication_03_PublisherTables.ps1** - After the publisher scripts are successfully executed, publication will be created under the replication folder. Note that this will take some time to complete. This creates publishers AXDB_PUB_TABLE_Obj_[*].

   **WARNING**
   
   Wait for data replication to complete before executing cutover scripts. You can check the status in the following ways:
   
   - Replication monitor: On the source server, right-click the Replication folder and select Launch Replication Monitor.
   - Run GetStatus.ps1 script embedded in the replication toolkit. **DataReplicationStatus** must be set to complete for each AXDB_PUB_TABLE_Obj_[*] publication.

4. **Replication_04_PublisherOtherObjects.ps1** - Replicates functions to the target database by creating new publication. This step can be omitted if you don’t want to move functions. Note that this will be completed quickly. This creates publisher AX_PUB_OtherObjects.

5. **CutOver_01_PublisherNoPK.ps1** - This creates two publications to replicate: - Non-primary key tables
   - Locked tables with publication names: AX_PUB_NoPKTable, AXDB_PUB_TABLE_Locked

6. **CutOver_02_PKDeletion_PostReplication.ps1** - This will clean up the temp tables created for tables with no primary keys. Deletes publication AX_PUB_NoPKTable.

7. **CutOver_03_RetrieveAndCreateNoPKConstraints.ps1** - This extracts constraints for the tables with no primary keys from the source and creates them in the target database.

8. **CutOver_04_RemoveReplication.ps1** - After successful replication of the database, you can execute this script to remove replication setup information. If you want to remove the snapshot folder without errors, execute the following stored procedure in the source Db. Otherwise, after execution you will get an error that the system was unable to remove the snapshot folders, which should be removed manually.

```sql
EXEC master.dbo.sp_configure 'show advanced options', 1
RECONFIGURE WITH OVERRIDE
EXEC master.dbo.sp_configure 'xp_cmdshell', 1
RECONFIGURE WITH OVERRIDE
```

The following publications will get created in the source database when setting up the replication.
Find the replication status and get an exception

To find the replication status and get an exception, execute the PowerShell script and wait for it to finish.

**GetStatus.ps1** - When you execute this script, the Replication status table will be listed, along with the schema AgentId, PublicationName, Job, LastSynced, JobStatus, ReplicationStatus, and Comments.

- **AgentId** - Used to fetch the exception details about the job.
- **PublicationName** - The publication names created for replicating the data. You can find the same information in the SQLServerExplorer under Replication folders.
- **Job** - There are two types of jobs: Snapshot and Data Replication.
- **JobStatus** - This will display the statuses of Started, Succeeded, In Progress, Idle, Retrying, or Failed. For snapshot jobs, after the status is Succeeded this will no longer execute. For data replication jobs, the status will continue to change based on the update information in the database.
- **ReplicationStatus** - This applies only to the data replication jobs. Statuses include Waiting, In Progress, and Completed.
- **Comments** - This will continue to change when the JobStatus is InProgress.

**GetException.ps1** - Provide the AgentId to get the exceptions. AgentId can be retrieved from the status.

Find the replication configuration and status via SQL Server Management Studio

To find the replication status configuration and status using SQL Server Management Studio, follow these steps:

- To determine if the replication feature is available and installed on the server, you should see the Replication folder in Object Explorer.
After executing the `Replication_03_PublisherTables.ps1` script, you should be able to see the publisher configured under the Replication folder.

To determine the replication status, right-click the Replication folder and select Launch Replication Monitor.
In the Replication Monitor window, you can see all the publishers that have been created for replication.

Select the Snapshot tab to see the status of the snapshot.

To view the detail log/transaction, double-click the item.
To view the data replication to the target, select the **All Subscription** tab and double-click the subscription for the item.

</table>
This Microsoft Dynamics AX 2012 data upgrade process is for self-service environments. Complete the sections of this topic in the following order:

1. **Prerequisites**
2. **Data upgrade process** – Run the AX2012DataUpgradeToolKit.exe application to complete the upgrade process.
3. **Reporting section of the application** – Review the reports of the replication validation, replication status, data upgrade status, and rollback data upgrade status.
4. **Tooling section of the application** – This section will help you reset the process parameters and restart any of the processes.
5. **Troubleshooting**

### Prerequisites

1. Download the AX 2012 Database Upgrade Toolkit for Dynamics 365 from Microsoft Dynamics Lifecycle Services (LCS). In the Shared asset Library, select **Model** as the asset type, and then select the model file.

2. Create a self-service environment in LCS. The environment should be in a **Deployed** state. It must be a Microsoft-managed environment. Cloud-hosted, development environments can be used only for the Upgrade from AX 2012 - Data upgrade in development environments procedure.

3. Download and install the .NET Framework version 4.7.1 if it isn't already installed.

4. Make sure that the replication feature is installed and enabled for the source SQL Server instance. To determine whether replication is enabled, run the following SQL script.

   ```sql
   -- If @installed is 0, replication must be added to the SQL Server installation.
   USE master;
   GO
   DECLARE @installed int;
   EXEC @installed = sys.sp_MS_replication_installed;
   SELECT @installed;
   
   If the replication components aren't installed, follow the steps in Install SQL Server replication to install them.

5. Enable and start the SQL Server Agent on the source database server.

   **NOTE**
   
   A user should have the **DB_Owner** privilege in the source database, and should have access to the master database and the source database.
6. **Migration toolkit setup:** If you don’t want some of the source database tables to be replicated in the target database, you can specify them in the IgnoreTables.xml file. Likewise, if you don’t want some of the functions to be replicated, you can specify them in the IgnoreFunctions.xml file.

- **Path of the IgnoreTables.xml file:** `Data\IgnoreTables.xml`
- **Path of the IgnoreFunctions.xml file:** `Data\IgnoreFunctions.xml`

The following examples show how to specify tables and functions in the XML files.

```xml
<?xml version="1.0" encoding="utf-8"?>
<IgnoreTables>
    <Name>
        <Table>NON_AOT_TABLE1</Table>
        <Table>NON_AOT_TABLE2</Table>
        <Table>NON_AOT_TABLE3</Table>
    </Name>
</IgnoreTables>
```

**NOTE**

The tables added to the ignore list should only be tables that do not exist in the Microsoft Dynamics AX 2012 Application Object Tree (AOT). Including tables that exist in the AOT will result in an error during the data upgrade.

```xml
<?xml version="1.0" encoding="utf-8"?>
<IgnoreFunctions>
    <Name>
        <Function>if_WHSInventReserveUnionDelta</Function>
    </Name>
</IgnoreFunctions>
```

**IMPORTANT**

The tables and functions that are specified in these XML files won’t be replicated in the target database, and the same format should be followed.

7. To optimize the replication latency/performance, you can update the following distributor parameters in the `App.config` file:

- **MaxBcpThreads** – By default, this parameter is set to 6. If the machine has fewer than six cores, update the value to the number of cores. The maximum value that you can specify is 8.
- **NumberOfPublishers** – By default, this parameter is set to 2. We recommend that you use this value.

**NOTE**

Do not set up or configure replication during peak times when the system resources/memory usage/IO operations are high. When resources are being used to the max (greater than 90% is already consumed) then the replication may be delayed as the system tries to find available resources. We recommend that you start the replication during off hours, when the system resources are at minimum usage (during off-peak time). Additionally, it is recommended for a go-live cutover that you start the replication the prior weekend.

---

**Data upgrade process**

**Run the AX2012DataMigration.exe application**
Before you begin the replication process, note that the LCS environment will be in a **Deployed** state when it’s created.

1. Run the **AX2012DataMigration.exe** application.
   
   A console window will open, and it prompts you to sign in.

2. Provide the credentials that are used to sign in to LCS.

3. After you’re successfully authenticated, in the console window, provide the **Project-Id** value and then the **Environment-Id** value.

   To validate the given values, you will need to sign in using the credentials that are used to sign in to LCS.

   **NOTE**
   
   You can find the **Project-Id** and **Environment-Id** values on the **Manage environment** page in LCS. You can also find the **Environment-Id** value on the **Environment details** page.

**Complete the data replication and upgrade**

After the validation is successful, the application presents a set of menu options that correspond to the steps in the data upgrade process. To complete the data replication and upgrade, you should perform the steps in the following order.

1. **Data upgrade preparation: Environment setup activity**

   This step prompts you for the following information:

   - **Details of the source database**:
     
     - Source server (in the format `servername\serverinstance`)
     - Source database name
     - User name
     - Password
   
   - **IP address of the source database server** (for the allowlist)
   
   - **Distribution database path** (for example, `D:\SQLServer\Data`)
   
   - **Replication snapshot path** (for example, `D:\SQLServer\Snapshot`)

   **IMPORTANT**

   The specified distribution database and replication snapshot paths should have enough space. We recommend that the amount of space be at least the size of the source database. The paths should be in the local disk of the machine. Avoid using shared paths.

   We recommend that you have a static IP address for the virtual machine (VM) or machine (for the allowlist in step 1). In this way, you help prevent connection issues with the target database.

   This step performs the following actions:

   - It validates the connection to the source database.
   - It validates the version of the AX 2012 database.
   - It authorizes the source IP address.
   - It validates the target databases.

2. **Data upgrade preparation: Prepare the target environment for the data upgrade**
This step changes the state of the LCS environment from **Deployed** to **Ready for replication**.

3. **Replication: Clean-up target database**

   This step performs the following actions:
   
   a. Change the state of the LCS environment from **Ready for replication** to **Replication in progress**.
   
   b. Delete all AX product tables, views, stored procedures, and user-defined functions in the target database.

4. **Replication: Set up distributor**

   This step creates a distribution database under the **System Databases** folder on the source server. This distribution database is used for replication.

5. **Replication: Set up publication for primary key tables**

   This step creates publications for primary key tables under the **Replication** folder on the source server and replicates them in the target database. If any **ignore-table** entries are specified, the specified tables are exempted from replication.

   **Created publishers:** AXDB_PUB_TABLE_Obj_*

   **NOTE**
   
   After this replication configuration step is completed, actual data replication will occur as a SQL job that runs in the background. This job will take some time to be completed. You can view the status of the replication by providing the ‘rs’ option. To learn more about the ‘rs’ option, see the Reporting section of the application section later in this topic.

6. **Replication: Set up publication for other objects (functions)**

   This step creates a publication for other objects (functions) and replicates them in the target database. If you don’t want some of the functions to be replicated, you can specify them in the IgnoreFunctions.xml file.

   **Created publisher:** AX_PUB_OtherObjects

   **NOTE**
   
   The replication will take some time to be completed. You can view the replication status by providing the ‘rs’ option.

   If there are no functions to replicate, the publication won’t be created.

   Don’t move on to next step until the **DataReplicationStatus** property for this step is shown as completed.

7. **Cutover: Set up publication for non-primary key tables**

   This step creates two publications: one that is used to replicate non-primary key tables, and one that is used to replicate locked tables.

   **NOTE**
   
   If there are no locked tables, then publication will not be created.

   **Publication names:** AX_PUB_NoPKTable, AX_PUB_TABLE_LockedTable

   If AX Service acquires a schema lock during creation of the primary key publication, those tables will be
ignored and omitted from the publication. They will be added to temporary tables and marked for replication during creation of the cutover publication.

**[IMPORTANT]** Don’t move on to next step until the **DataReplicationStatus** property for this step is shown as completed.

8. **Cutover: Remove non-primary key publication and temporary tables**

**[IMPORTANT]** This step only applies to customers using **AX 2012 Database Upgrade Toolkit for Dynamics 365** app version 8 or earlier.

This step performs the following actions:

a. Clean up the temporary tables that were created for non-primary key tables in the source database.

b. Delete the **AX_PUB_NoPKTable** publication.

You can validate the replicated data by using the ‘dv’ option. If there are mismatched tables, this step lets you create publications for them. If you want to exclude any mismatched tables for replication, close the app, and add those tables in **Data/IgnoreTables.xml**. Then rerun the app, and use the ‘dv’ option.

To learn more about the ‘dv’ option, see the **Reporting section of the application** section later in this topic.

9. **Cutover: Create constraint for non-primary key tables**

**[IMPORTANT]** This step only applies to customers using **AX 2012 Database Upgrade Toolkit for Dynamics 365** app version 8 or earlier.

This step extracts constraints for the non-primary key tables from the source database and creates them in the target database.

10. **Cutover: Remove replication setup**

This step deletes all the publications that were created in the source database, the distribution database, and the replication snapshot.

**NOTE**

To remove the **Snapshot** folder without causing an exception, run the following script in the source database.

Even if you don't run this script, you can ignore the exception message that you receive.

```sql
EXEC master.dbo.sp_configure 'show advanced options', 1
RECONFIGURE WITH OVERRIDE
EXEC master.dbo.sp_configure 'xp_cmdshell', 1
RECONFIGURE WITH OVERRIDE
```

11. **Post-replication: Update environment state to Replicated**

This step changes the state of the LCS environment from **Replication in progress** to **Replication completed**.

12. **Data upgrade: Trigger upgrade**
This step triggers the data upgrade. When the action is successful, the state of the LCS environment changes from **Replication completed** to **Data upgrade in progress**.

At this point, only the data upgrade trigger occurs. The actual data upgrade occurs in the self-service environment. To learn the status of the data upgrade, use the ‘ds’ option. To learn more about this option, see the Reporting section of the application section later in this topic.

If data upgrade is successful, the ‘ds’ option is shown as **AX 2012 upgrade topology (LCS) status: Deployed**, and all the upgrade steps will be in a **Completed** state.

If data upgrade fails, the ‘ds’ option is shown as **AX 2012 upgrade topology (LCS) status: Failed**, and one or more upgrade steps will be in a **Failed** state. The **Menu option (12)** tool will show a status of **Resume**.

After you address and fix the reasons for the failure, you can perform the **Resume** operation. When the action is successful, the state of the LCS environment will change from **Failed** to **Data upgrade in progress**.

NOTE
Repeat this step until the data upgrade is successful.

13. **Rollback data upgrade: Trigger rollback**

This step triggers the rollback of data upgrade. This rolls back the data to the point before the upgrade is triggered and sets the LCS environment state to **Replicated**. This will change the environment from **Failed** to the **Replicated** state.

At this point, you have only triggered the rollback. To see the rollback status, use the ‘rbs’ option. To learn more about this option, see the Reporting section of the application later in this topic.

If rollback is successful, the ‘rbs’ option is shown as **AX 2012 upgrade topology (LCS) status: Replicated**.

If rollback fails, the ‘rbs’ option is shown as **AX 2012 upgrade topology (LCS) status: Failed**.

For more information about the data upgrade process, see Upgrade from AX 2012 – Data upgrade FAQ. This topic answers some frequently asked questions about data upgrade during an upgrade from Microsoft Dynamics AX 2012.

**Reporting section of the application**

You can use the following options to review the reports of the replication validation, replication status, data upgrade status, and rollback data upgrade status.

- **dv) Report**: Validate the replication.

  This option compares the number of tables and records in the source server database and the target server database, and then shows the report. You should use this option only after step 8 is completed.

  If there are mismatched tables, this step lets you create a publication for them. If you want to exclude any mismatched tables for replication, close the app, and add those tables in **Data/IgnoreTables.xml**. Then rerun the app, and use the ‘dv’ option.

  You can find the report data at **output/PostValidationInfo.csv**.

- **rs) Report**: Get the replication status.
This option shows the report of the replication process for the publications that were created. You should use this option only after step 5 is started (that is, during the replication process for any publication).

- **ds) Report**: Get the data upgrade status.
  
  This option shows the report of the data upgrade process. You should use this option only after step 12 is started.

- **rbs) Report**: Get the rollback status.
  
  This option shows the report of the rollback process. You should use this option only after step 13 has started.

**Tooling section of the application**

- **Reset-rep**: Reset the replication setup by removing all the replication configurations. Publications and the distribution database are deleted. The status of all Replication and Cutover menu options is reset from Completed mode to Reset mode to help you redo the replication from the beginning.
- **Reset-all**: Reset all the menu options, and remove the replication configurations. The status of all the options is changed to Not Started.
- **Clear**: Clear the environment setup activity. All information is cleared from the cache, such as the project-Id value, Environment-Id value, and source database details. The status of step 1 is changed to Not Started.
- **Help**: Show the data upgrade migration options with the updated status.
- **Exit**: Close the application.

**Troubleshooting**

- **Scenario 1**: The migration app is prompting you to enter Project-Id and Environment-Id values.

  **Solution**: The user should be part of the project and should be assigned to one of the following roles: ProjectOwner, EnvironmentAdmin, or OperationsAdmin.

- **Scenario 2**: Migration app database connectivity failed for the source database server or the target database server.

  **Solution**: In the migration app, complete step 1, Data upgrade preparation: Environment setup activity.

- **Scenario 3**: The snapshot for any of the publications failed. This failure can be tracked in the Replication Monitor.

  **Solution**: In the Replication Monitor, on the Agents tab, select the failed publication, select and hold (or right-click) the snapshot agent, and then select Start agent to generate a snapshot.

- **Scenario 4**: If one of the steps fails in the migration app, and you must rerun that step, follow these steps:
  1. Close the migration app.
  2. In the migration app folder, find the Data folder.
  4. In the file, you can see all the menu options that have the same ID sequence. Find the step that you want to rerun, and update the Status value to 0.
IMPORTANT

Don't change anything else in this file. When you update the file, make sure that the migration app isn't in a running state.

5. Open the migration app, and run the step.

- **Scenario 5:** After the publication is created, the replication job fails, and the following exceptions occur:
  
  - **Exception 1:**
    
    Cannot execute as the database principal because the principal "dbo" does not exist, this type of principal cannot be impersonated, or you do not have permission. (Source: MSSQLServer, Error number: 15517)
    
    Get help: [http://help/15517](http://help/15517)
  
  - **Exception 2:**
    
    The process could not execute 'sp_replcmds' on 'replicationsrv\MSSQLSERVER2016'. (Source: MSSQL_REPL, Error number: MSSQL_REPL20011)
    
    Get help: [http://help/MSSQL_REPL20011](http://help/MSSQL_REPL20011)

    Cannot execute as the database principal because the principal "dbo" does not exist, this type of principal cannot be impersonated, or you do not have permission. (Source: MSSQLServer, Error number: 15517)
    
    Get help: [http://help/15517](http://help/15517)

  **Solution:** In SQL Server Management Studio (SSMS), open a query window, connect to the source database, and run the following command:

  ```sql
  EXEC sp_changedbowner 'sa'
  ```

- **Scenario 6:** The LCS status is **Failed**. However, in the migration app, the data upgrade trigger is successful.

  **Solution:** In the migration app, run the 'ds' option. This option reads the LCS environment state and the data upgrade status for every step and substep.

  **NOTE**

  If the data upgrade status and the LCS environment status are **Failed**, the status of step 12 in the Complete the data replication and upgrade procedure will be updated to **Resume**. The user can then resume the operation from the point where the upgrade process failed.

- **Scenario 7:** If you want to skip the failed step (if that step was manually run) and proceed with further steps, follow these steps:

  1. Close the migration app.
  2. In the migration app folder, find the **Data** folder.
  3. In the **Data** folder, open the **ReplicationMenu.Json** file.
  4. In the file, you can see all the menu options that have the same ID sequence. Find the step that you
want to rerun, and update the **Status** value to 1. By changing the status to 1, you mark the step as completed.

**IMPORTANT**

Don't change anything else in this file. When you update the file, make sure that the migration app isn't in a running state.

- **Scenario 8**: To migrate from an old version to the new version of the console app, follow these steps:

  1. Download the latest version of the console app from LCS.
  2. Take the `paramsdata.txt` and `ReplicationMenu.json` files from the old version of the console app, and put them under the same paths in the new version of the console app.
  3. Rerun the app.

- **Scenario 9**: The replication status for any of the publications is shown as **Waiting for snapshot to complete** for more than two hours.

  **Solution**: In the Replication Monitor, select and hold (or right-click) the publication, and then select **Reinitialize Subscription**.

- **Scenario 10**: You want to resume the data upgrade.

  **Solution**: The data upgrade status might not have been updated in the console app. Follow these steps to resume the data upgrade:

  1. To learn the status of the console app, perform the **Help** option. This option lists all the menu options and shows the current state.
  2. In the **Complete the data replication and upgrade** procedure, if the status of step 12 is **Successful**, run the 'ds' option in the migration app. This option updates the data upgrade status.

  After the 'ds' option is run, two types of status will be listed: the LCS environment status and the data upgrade status.

  - **Case 1**: If the LCS environment status is **Failed**, and the last step of the data upgrade is **Failed**, step 12 will show the Resume option.
  - **Case 2**: If the LCS environment status is **Failed**, and the last step of the data upgrade is **Completed**, step 12 will show the Resume option.
  - **Case 3**: If the LCS environment status is **Deployed**, and the last step of the data upgrade is **Completed**, step 12 will show **Successful**.
  - **Case 4**: If the LCS environment status is **Deployed**, and the last step of the data upgrade is **In Progress**, step 12 will show **Successful**, because the data upgrade job is running in the background.

- **Scenario 11**: After creating the publication, if the snapshot creation fails with the following error.
Learn about the replication configuration and status via SQL Server Management Studio

Solution: In the Replication Monitor, select and right-click the failed publication, and then select Generate Snapshot.

In SSMS, if Object Explorer includes a Replication folder, the replication feature is installed on the server and available.

After step 3 of the data upgrade process is completed, you should find the publisher configured under the Replication folder. To learn the replication status, select and hold (or right-click) the Replication folder, and then select Launch Replication Monitor.

- In the replication monitor, you can view all the publishers that have been created for replication.
- On the Snapshot tab, you can view the status of the snapshot.
- To view the detail log/transaction, double-tap (or double-click) a grid item.
- To view the data replication to the target, on the All Subscription tab, double-tap (or double-click) the subscription from the grid item.
This topic describes the process for upgrading Microsoft Dynamics AX 2012 databases to Dynamics 365 Finance + Operations (on-premises) version 10.0.x. Currently, upgrade is supported only from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3.

### IMPORTANT

This topic explains the process for doing a data upgrade only. For information about how to do a code upgrade, see the upgrade guides that are available for cloud versions. The code upgrade tooling is available only through Microsoft Dynamics Lifecycle Services (LCS).

### AX 2012 upgrade to Dynamics 365 Finance + Operations (on-premises)

Two upgrade methods are currently supported:

- **Upgrade from inside the VHD** – This method involves copying your database into the virtual hard disk (VHD) and running the upgrade from inside the VHD. Overall, this method is easier.

- **Upgrade where the VHD points to your database** – This method involves pointing the VHD upgrade process to your database. The upgrade process is still run from inside the VHD.

### NOTE

The VHD doesn't require external network access to run the upgrade process.

### Prerequisites

1. Sign up for a preview subscription.

2. For each AX 2012 release, update to the most recent cumulative update that is available before you upgrade to the most recent Finance + Operations application release.

3. Install the pre-upgrade checklist. For more information, see [Installation](#).

4. Go through the data upgrade preparation steps. You can skip the “Set up user mapping” step. This step is relevant only for cloud-hosted upgrades.

5. Make a backup of your database (MicrosoftDynamicsAX). For more information, see [Create a Full Database Backup](#).

6. In LCS, go to the Shared asset library by selecting the tile on the right side of the page. Then, under **Select asset type**, select **Downloadable VHD**, and download all parts of the VHD package that most closely matches the version that you will upgrade to in your on-premises environment. The image requires a large amount of disk space. Therefore, be sure to download and extract the package on a drive that has enough free space.

7. The files that you downloaded are a self-extracting zip file. Extract the VHD to a location that has a good amount of free space.
8. Use Hyper-V to start a virtual machine (VM) and attach the VHD. (Note that the VM must be Generation 1.)

9. Connect to the VM. For information about the credentials, see Running the Virtual Machine (VM) locally.

10. Depending on your planned on-premises target version of 10.0.x and the VHD image that you downloaded, you might have to download and apply the required application update and platform update from the Shared asset library. Under Select asset type, select Software deployable package. For more information, see Install deployable packages from the command line.

   **IMPORTANT**
   In any case, make sure that you've applied the most recent quality update to your VHD, to ensure that it contains the most recent fixes for doing data upgrades.

11. If you have any extensions or customizations, install them on the VHD now. Otherwise, the upgrade process will remove any data that is related to customizations. If you must prepare your environment before the upgrade, check with your independent software vendor (ISV) or value-added reseller (VAR).

   **Upgrade from inside the VHD**
   1. Restore the backup that you created to the OneBox VM. For more information, see Restore a Database Backup Using SSMS.

   2. Optional: If the name of your restored database isn't AXDB, open Windows PowerShell as an administrator, and run the following script.

   ```powershell
   .\Configure-On-Premises-Upgrade.ps1 -DatabaseName '<DB-name>'
   ```

   **NOTE**
   Replace `<DB-name>` with the name of your database (for example, AXDB). If you want to edit more values, see the appendix later in this topic.

   The script will run a database connection test to verify that the information that you provided is valid.

   3. In LCS, go to the Shared asset library. Under Select asset type, select Software deployable package, and then select AX2012DataUpgrade-10-0-8 to download the MajorVersionDataUpgrade.zip file.

   4. Copy the file, paste it in the desired location (for example: c:\D365FFOUpgrade\), and unzip it.

   5. Open a Command Prompt window as an administrator, change the directory to the folder that you just unzipped, and run the following commands.

   ```powershell
   AxUpdateInstaller.exe generate -runbookid=upgrade -runbookfile=upgrade.xml -topologyfile=defaulttopologydata.xml -servicemodelfile=defaultservicemodeldata.xml
   AxUpdateInstaller.exe import -runbookfile=upgrade.xml
   AxUpdateInstaller.exe execute -runbookid=upgrade
   ```

   6. After the upgrade process is successfully completed, back up the newly upgraded database. If you have customizations from ISVs or VARs, check whether you must run some post-data upgrade scripts.

   7. Restore the database into your on-premises environment's SQL Server, but give it a name that differs from the name of the AX 2012 database (for example, name it AXDBUpgraded). The restored database must be configured. Follow the steps in Configure the Finance + Operations database.

If you have customizations, follow these steps:

a. In LCS, go to the Shared asset library.

b. Under Select asset type, select Model, and then download Dynamics 365 Finance + Operations on-premises, Version 10.0.x Demo Data. Select the version that is closest to the 10.0.x environment that you will deploy as the on-premises baseline.

c. Use the restore backup option for SQL Server to create a new database from this file. (Typically, this database is named AXDB.) For more information, see Restore a Database Backup Using SSMS.

d. The demo database must be configured. Follow the steps in Configure the Finance + Operations database.

e. In LCS, set up a new environment, and deploy it with version 10.0.x. For more information, see Set up and deploy on-premises environments (Platform update 12 and later). When you deploy the environment, the name of the database that you specify should be the name of the database that you created earlier (typically AXDB).

f. Apply your own customizations, and ISV and VAR modules, to the newly created 10.0.x environment. Otherwise, when the environment is initially synced with the database, it will delete any customization-related or extension-related data.

If you don't have customizations, follow these steps:

a. Optional: Rename your old database (typically AXDBold), and then rename your new database (typically AXDB). In the next step, make sure that you enter the name of the upgraded database.

b. In LCS, set up a new environment, and deploy it with version 10.0.x (Redeploy). For more information, see Set up and deploy on-premises environments (Platform update 12 and later).

**Upgrade where the VHD points to your database**

1. Back up the database from your on-premises environment (typically AXDB). For more information, see Create a Full Database Backup (SQL Server).

2. Restore the backup that you just created into the database server, and give it a different name (for example, AXDBtoupgrade). For more information, see Restore a Database Backup Using SSMS.

3. Open Windows PowerShell as an administrator, and run the following script.
.\Configure-On-Premises-Upgrade.ps1 -DatabaseName 'DB-name' -DatabaseServer 'SqlServerName' -DatabaseUser 'User' -DatabasePassword 'Password'

NOTE
- Replace <DB-name>, <SqlServerName>, <User>, and <Password> with the values that you require.
- Only SQL Server authentication is officially supported for this upgrade. For more information, see Create a Database User.
- You must add the certificate authority certificate that signed your SQL Server certificate to the trusted certificate authorities store in your Onebox VHD. For more information, see Installing the trusted root certificate.
- Make sure that the database user that you use has the sysadmin server role, or at least All Privileges, assigned on the database that you want to upgrade. Also make sure that the user has permissions to access tempDB. Step 6 of the upgrade process will fail if these conditions aren't met.
- When you install the certificate authority certificate in the OneBox VHD, make sure that you use the fully qualified domain name (FQDN) or IP address to connect to the database that appears there. If you can't access the database by using the domain name, because it doesn't point to that server, edit your hosts file, and add the FQDN and the IP address that the FQDN should be resolved to.

4. In LCS, go to the Shared asset library. Under Select asset type, select Software deployable package, and then select AX2012DataUpgrade-10-0-8 to download the MajorVersionDataUpgrade.zip file.

5. Copy the file, paste it in the desired location (for example: c:\D365FFOU...4\), and unzip it.

6. Open a Command Prompt window as an administrator, change the directory to the folder that you just unzipped, and run the following commands.

   a. AxUpdateInstaller.exe generate -runbookid=upgrade -runbookfile=upgrade.xml -topologyfile=defaulttopologydata.xml -servicemodelfile=defaultservicemodeldata.xml
   b. AxUpdateInstaller.exe import -runbookfile=upgrade.xml
   c. AxUpdateInstaller.exe execute -runbookid=upgrade

7. If you have customizations from ISVs or VARs, check whether you must run some post–data upgrade scripts.

8. Run the Configure-OnpremUpgrade.ps1 script by using the values that are stated in the Resetting the VHD database (Optional) section later in this topic.

9. Configure your upgraded database for Finance + Operations by following the steps in Configure the Finance + Operations database.

10. Deploy a new Dynamics 365 Finance + Operations (on-premises) environment.
    - If you have customizations, follow these steps:
      a. In LCS, go to the Shared asset library.
      b. Under Select asset type, select Model, and then download Dynamics 365 Finance + Operations on-premises, Version 10.0.x Demo Data. Select the version that is closest to the 10.0.x environment that you will deploy as the on-premises baseline.
      c. Use the restore backup option for SQL Server to create a new database (typically AXDB) from this file. For more information, see Restore a Database Backup Using SSMS.
      d. The demo database must be configured. Follow the steps in Configure the Finance + Operations database.
      e. In LCS, set up a new environment, and deploy it with version 10.0.x (Redeploy). For more
Configuring existing users

If you followed either of the previous procedures, you can sign in by using the Administrator user that you specified in LCS. However, none of your other users can sign in until they have been configured for the new system. Run a `Select` statement against your USERINFO table, and make a note of the value in the `NETWORKDOMAIN` field for the Administrator user (for example, `https://adfs.contoso.com/adfs` or `http://adfs.contoso.com/adfs/services/trust`). Then, for all interactive users who should be able to sign in, set the `NETWORKDOMAIN` field to the same value that the Administrator user has. The `NETWORKALIAS` field must also be modified. In Finance + Operations, this field is set to the user’s email address (for example, `testuser@contoso.com`).

Reseting the VHD database (Optional)

If you used the `Configure-On-Premises-Upgrade.ps1` script, run the following command to reset your database to the default configuration.

```
\Configure-OnPremUpgrade.ps1 -DatabaseName 'AXDB' -DatabaseServer 'localhost' -DatabaseUser 'axdbadmin' -DatabasePassword 'AOSWebSite@123'
```

Appendix

Using the Configure-On-Premises-Upgrade.ps1 script
This script is intended to be run only from a OneBox VHD environment. The script requires that you pass at least the `DatabaseName` parameter. If you don’t pass this parameter, the script automatically requests it.

You can pass an additional parameter, such as `DatabaseServer` or `DatabaseUser`, if you want. However, in this case, the script will request all additional parameters. This behavior occurs because the script will assume that you want to point the database connection to a machine outside the VM. Therefore, those parameters are required to correctly establish the connection.

The following parameters can be passed to the script:

- `-DatabaseName` – The name of the database to upgrade.
- `-DatabaseServer` – The database server that contains the Finance + Operations database.
- `-DatabaseUser` – The user name for SQL Server Authentication.
- `-DatabasePassword` – The password for SQL Server Authentication.

After the configuration has been passed, the script uses the new parameters to run a database connection test. If the script can’t connect to the database, we recommend that you debug the connection from SQL Server Management Studio or another tool.

```powershell
<#
.Synopsis
    Configures a OneBox deployment to upgrade an OnPrem 7.x database to OnPrem 10.0.x

.DESCRIPTION
    This must be executed before the upgrade process is carried out.

.EXAMPLE
    .\Configure-OnPremUpgrade.ps1 -DatabaseName 'AxDB'

    .\Configure-OnPremUpgrade.ps1 -DatabaseName 'AxDB' -DatabaseServer '127.0.0.1' -DatabaseUser 'axdbadmin'
    -DatabasePassword 'secretPass'
#>
[CmdletBinding()]
param
(
    # Database server containing Microsoft Dynamics 365 for Operations, on-premises database.
    [AllowNull()]
    [string] $DatabaseServer,

    # Database name that you want to upgrade.
    [Parameter(Mandatory = $true)]
    [string] $DatabaseName,

    # Username for SQL Authentication.
    [AllowNull()]
    [string] $DatabaseUser,

    # Password for SQL Authentication.
    [AllowNull()]
    [string] $DatabasePassword
)
$webroot = "C:\AOSService\webroot"
$commandParameter = " -decrypt "$webroot\web.config""
```
$command = Resolve-Path "$webroot\bin\Microsoft.Dynamics.AX.Framework.ConfigEncryptor.exe"

Start-Process $command $commandParameter -PassThru -Wait

if([string]::IsNullOrEmpty($DatabaseUser) -and [string]::IsNullOrEmpty($DatabasePassword) -and [string]::IsNullOrEmpty($DatabaseServer)) {

}

## Troubleshooting

- Exception calling "Open" with "0" argument(s): "Cannot open database "AxDB1" requested by the login. The login failed. Login failed for user 'axdbadmin'." You supplied the Wrong database name or the user doesn't have access to that database.
- Exception calling "Open" with "0" argument(s): "A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found or was not accessible. Verify that the instance name is correct and that SQL Server is configured to allow remote connections. (provider: Named Pipes Provider, error: 40 - Could not open a connection to SQL Server)". The script could not establish a connection with the SQL Server specified. Check the ip/fqdn and port that you used.
- Exception calling "Open" with "0" argument(s): "Login failed for user 'axdbadmin'." The supplied login credentials are not correct.
Cutover is the term that we use for the final process of getting a new system live. The cutover process consists of the tasks that occur after Microsoft Dynamics AX 2012 is turned off, but before Finance and Operations is turned on. The purpose of upgrade cutover testing (mock cutover) is to practice the cutover process, to help guarantee a smooth experience for everyone who is involved during the actual cutover to go-live.

There are three main workstreams during a cutover:

- **Technical workstream** – This workstream includes the data upgrade execution process. Your business will enforce a limit on the amount of downtime that is allowed. During this downtime, neither AX 2012 nor Finance and Operations will be available. This workstream might have to tune the data upgrade procedure to meet the business’s downtime limit.

- **Functional workstream** – This workstream includes the configuration tasks that are performed after the data upgrade is completed. All these tasks must be documented and quantified, and a resource must be assigned, because both the functional workstream and the technical workstream must fit within the business’s downtime limit.

- **AX 2012 rollback** - This workstream includes rolling back to an AX 2012 environment. Although it’s unlikely that you will have to roll back, it’s very important that you have a tested process in case you require it.

The following illustration shows the overall process for cutover to go-live as it will occur in the production environment.

The mock cutover process is very similar to data upgrade validation in a sandbox environment. We assume that you are familiar with that process, and have already performed it. Mock cutover differs in the following ways:

- After you perform a data upgrade in the sandbox environment, see the instructions in **Self-service database refresh** to copy your upgraded database from the data upgrade sandbox environment into your production environment.

- We added the following tasks:
Technical workstream

The technical workstream involves various technical team members: the database administrator (DBA), the AX 2012 system administrator, server administrators, and developers who are familiar with AX 2012 and Finance and Operations.

During cutover testing, the technical team is focused on performance and reliability testing of the data upgrade process, to make sure that it meets the business’s downtime limit. Many elements of hardware and software are involved in this process. Some of these elements are on-premises, whereas others are in the Microsoft cloud. In addition, many elements of custom application code and standard code are involved. The result of this testing should be confidence in the cutover process for your environment.

Technical workstream process

For the technical workstream, the cutover testing process is the same described in Upgrade from AX 2012 - Data upgrade in self-service environments.

Functional workstream

After data upgrade, several configuration tasks will be required in the new environment. The goal of this workstream is to document and quantify all configuration tasks, and to assign a resource to each task, to help guarantee that these tasks can be done together with the technical workstream during the downtime window.

Typically, functional tasks involve changing the values of specific system parameters or other configuration data. These tasks are identified through the full functional test pass, which is a separate activity from the cutover testing. When a task of this type is identified, it should be reviewed together with the functional resource and your developer.

Larger changes might require that a new custom data upgrade script be written to update the data during the data upgrade process. However, the functional resource can manually run smaller changes through the new system after data upgrade.

Larger changes that have new data upgrade scripts must be tested. Therefore, one or more additional iterations of the MajorVersionDataUpgrade.zip package will have to be run. It’s important that you weigh the cost of running the package again against the cost of manual data entry.

For each manual change, a task must be added to the cutover plan document. This task must show the following details:

- Perform a smoke test.
- Complete application setup tasks. This step can be large, depending on the functionality that is used. During this step, the functional team configures new application functionality so that it’s ready to be used in the upgraded system.
- Allow users back in. Notify your user base that the upgrade is completed and that they can use the system again.
• What is the task, and what must be done?
• Who must do it?
• How long does it take?

**Add users, and perform functional tests**
When you have fully configured your environment, add users, and perform appropriate testing.

**Roll back to AX 2012**
The goal of this task is to restore the database by using the backup that was made when AX 2012 was turned off, and then turn AX 2012 back on. The state of integrated systems might also have to be restored. However, because integrated systems vary from business to business, you must plan for this scenario independently, based on your specific circumstances. Although it's unlikely that you will have to roll back, it's very important that you have a tested process in case you require it.
This topic describes the tasks that you might have to perform in Finance and Operations apps, like Dynamics 365 Finance and Dynamics 365 Supply Chain Management, after you complete a code and data upgrade from Microsoft Dynamics AX 2012. A process data package (PDP) that is available in Microsoft Dynamics Lifecycle Services (LCS) includes links to the following menu items. This PDP will fill in the Data validation checklist workspace. The Data validation checklist workspace lets users track a project and monitor the tasks that are required in order to complete it.

Document management

If you use document management, existing documents or attachments that are stored in the database should be migrated to Microsoft Azure Blob storage. To complete this migration, use the Migrate files button on the Migrate files tab on the Document management parameters page. This operation is not critical as document management can still access file stored in the database, but the files can take considerable database storage and the retrieval is less efficient. The file migration process will migrate all possible database files to Microsoft Azure Blob storage, reporting on any failures and continuing. If any errors are reported, attempt running the file migration process again.

If the file migration process isn’t able to complete without failure, this may be that the files stored in the database are corrupt, which Microsoft is unable to repair. If this is the case, you can request a non-business critical support case be opened to enable conversion of the attachments into note records, which will retain any previous notes as well as the names of the files that were stored in the database. Note that the files themselves cannot be recovered.

Print management

If you use Print management, the references to network printers from AX 2012 won’t be valid. You must set up and reference network printers on the Document routing page. For more information, see Install the Document Routing Agent to enable network printing.

Commerce

After you complete the upgrade from AX 2012, you must configure registers and devices.

To configure a register, click Retail and Commerce > Channels > Stores. Select the row for the channel, and then expand the Registers FactBox. Click More, click New, and complete the setup of the register.

To configure a device, click Retail and Commerce > Channel setup > POS Setup, and then click New.

Additionally, you must run all jobs (9999) for the channel database. Click Retail and Commerce > Headquarters setup > Commerce scheduler > Channel database. Select the row for the appropriate channel database, and then click Full data sync. Select the 9999 (All jobs) distribution schedule, and then click OK. Click OK again to run the job.
Service industries

After you complete the upgrade from AX 2012, you must set up resource capacity roll-up and project ledger intercompany posting.

To run the Resource capacity roll-up batch job, click Project management and accounting > Inquiries and reports > Capacity synchronization. You must run this batch job to set up the resource and resource calendar reservation data. This data will be required if you use project resource scheduling. For more information, see Project resourcing.

To enable project ledger intercompany posting, click Project management and accounting > Setup > Posting > Ledger posting setup. On the Cost accounts tab, in the Ledger account types field, select Intercompany cost, and then enter the details of the lending legal entity. On the Revenue accounts tab, in the Ledger account types field, select Intercompany revenue, and then enter details of the borrowing legal entity.

Budget planning

After you complete the upgrade from AX 2012, you must set up Budget planning columns and layouts. To complete this setup, click Budgeting > Setup > Budget planning > Budget planning configuration.

Additionally, you must update Budget planning processes so that they use the appropriate layout for each budget stage. To update Budget planning processes, click Budgeting > Setup > Budget planning > Budget planning process.

For more information about Budget planning upgrade, see Upgrade budget planning.
IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

After data upgrade is completed, we recommend that you complete a full functional test pass of all business processes. In a full functional test pass, you do an extensive retest of all business processes that are performed by using Finance and Operations. Tests should include both processes that have been brought forward from Microsoft Dynamics AX 2012 and new processes that use features from Finance and Operations.

Depending on your code quality, bug remediation and retesting might require several iterations of the functional test pass. After a bug is fixed, take care to retest all processes that are involved, to make sure that no downstream or upstream processes are affected by the change.

Old data vs. new data

As you create a list of tests to perform, consider the impact of old data versus new data. This type of testing will help you uncover data-related bugs. The code that created the old and new data might be very different, and this difference can be a common root cause of bugs.

For example, if the business process that you’re testing is cancellation of a purchase order, can you cancel a purchase order that was started before it was upgraded to the new system? Can you also cancel a purchase order that was started after the upgrade to the new system?

We used a very simple example here, but the testing requirement can be more complex, because many business processes in the system are interconnected, and the effect of old data versus new data effect is cumulative.

For example, here are the stages of a production test flow:

1. The item master is designed and released to a legal entity.
2. Item requirements are created.
3. Production orders are generated.
4. Purchase orders are generated.
5. Production order processing occurs (shop floor).
6. Vendor payment (payment of purchase orders) occurs, and so on.

In this production test flow, each stage can be performed by using either new records or old records as input. The result is a matrix of tests that covers every combination of old and new data. For some processes, test matrices might seem excessive, and they might actually be excessive in practice. Therefore, you can decide to focus on certain combinations that you predict will be used the most. However, it’s still helpful for you to know what you aren’t covering. Make a conscious decision, where you know what you have, what you’re going to focus most of the testing on, and what you’re not going to focus on.
IMPORTANT

Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

As the go-live date approaches, it’s important that you implement this series of steps to help ensure that the source Microsoft Dynamics AX 2012 system and the upgrade process both remain stable and consistent for go-live.

As part of this process, you must lock down any further code changes or application setup changes before you run the final cutover test.

Code freeze

All code changes in the AX 2012 environment should be frozen. Implement an escalation process to handle any critical issues that appear in AX 2012. By default, any new code changes that are required should be implemented only in the new system, not in the AX 2012 environment. Implementation of proposed code changes in the AX 2012 environment should be discussed at the management level. If a code change is made in AX 2012, the same change must be made in the new system. In that case, another iteration of cutover testing and functional testing might be required.

Application configuration freeze

All application configuration changes should be frozen in the AX 2012 environment, because these changes could affect how the new system behaves or how the data upgrade scripts behave. Configuration changes are changes in the AX 2012 application that are related to the configuration of system functionality. By freezing these changes, you help guarantee the stability of the data upgrade process.

Because configuration changes are typically controlled by the AX 2012 system administrator or a small group of trusted super users, we don’t recommend that you enforce the freeze by changing security access. Instead, implement the freeze through a business process that is communicated to those users. Changes to security access might require a code change (changes to the role definitions themselves) or a configuration change (reassignment of users), and these changes could affect the upgrade process.

Running the final cutover test

After no further code or setup changes will occur, run a final cutover test to make sure that all data and code upgrade tasks still run as expected.

NOTE

You must complete this step even if you freeze code and setup changes at the beginning of the upgrade project, because the data itself changes every day. This final cutover test also validates that the current data is upgraded successfully.

Make sure that functional testing is performed against this last upgraded copy.

At this point in the upgrade project, we recommend that you categorize any bugs that are found:
- **Blocking** – The upgrade project can’t proceed until every bug of this type is fixed. The upgrade must be postponed, and can proceed only after the bug is remediated and the cutover test is run again. For a bug to be classified as blocking, it must meet these conditions:
  - It prevents a critical business process from being completed.
  - No workaround or mitigation is available for it.
- **Non-blocking** – The upgrade project can proceed. Bugs of this type can be fixed in the upgraded system.
IMPORTANT
Upgrade is currently only supported from either Dynamics AX 2012 R2 or Dynamics AX 2012 R3. For each release, please update to the latest available cumulative update before upgrading to latest Finance and Operations application release.

After you have successfully completed upgrade testing in a Standard or Premier Acceptance Test environment (Sandbox Tier 2 or higher), and you have also completed a successful test cutover, the time has arrived to upgrade your production environment and go live.

Cutover is the term that we use for the final process of getting a new system live. This cutover process consists of the tasks that occur after Microsoft Dynamics AX 2012 is turned off but before Finance and Operations is turned on. Before you plan your final cutover, you need to successfully complete one successful mock cutover as described in Cutover testing.

The following illustration shows the overall process for cutover to go-live as it will occur in the production environment.

NOTE
In this topic, we use the term sandbox to refer to a Standard or Premier Acceptance Testing (Tier 2 or 3) or higher environment connected to a SQL Azure database.

Overall process
The high-level steps of the production environment upgrade process are the same as the Mock cutover process, refer to Upgrade from AX 2012 - Cutover testing (Mock cutover) for detailed instructions.

1. Be sure you've completed the pre-upgrade checklist for data upgrade and custom code is deployed in a sandbox environment. The sandbox environment must only be used for data upgrade.

2. Download the AX 2012 Database Upgrade Toolkit for Dynamics 365 from Microsoft Dynamics Lifecycle Services (LCS) in the Shared asset library > Model area. Use this toolkit from the source SQL Server.

3. Execute replication setup and keep monitoring it on a regular basis using the toolkit.

4. Turn off the AX 2012 AOS instances at the time of downtime/cut-over.

5. Ensure replication completes. Validate replication completion by comparing the number of records between...
source and target using this toolkit. For more information about how to validate the replication, see Reporting section of the application.

6. Execute cutover steps using the toolkit and ensure its completion.
7. Trigger the data upgrade using the toolkit and finish the data upgrade.
8. Use Self-service database refresh process to copy your upgraded database from the sandbox environment into your production environment.
9. Complete application configuration and complete smoke test.
10. Allow users to access the Finance and Operations app again.

Prerequisites

Before you can perform an upgrade in the production environment, the following prerequisites must be met:

- Complete the code upgrade and data upgrade in a sandbox environment and successfully complete a functional test pass.
- Deploy the production environment. Before the option to request the deployment of the production environment is an option, you must have completed:
  - The Subscription estimator in LCS. We use this to help us size your production environment because it provides details of the throughput you’ll require.
  - The Test phase of the methodology in LCS. This is to help ensure that you’re at the stage in your project where you’re ready to start testing in the production environment.
  - After a request is submitted to Microsoft to deploy the production environment, it will take roughly 24 hours to deploy, so ensure that you leave enough time for this to happen.
- Apply all necessary updates and customizations (AOT deployable packages) to the production environment. There should not be any code change after signing off on a Mock cutover.

Additional resources

- Onboarding
- Self-service database refresh
- Upgrade from AX 2012 - Cutover testing (Mock cutover)
This topic answers some frequently asked questions about data upgrade during an upgrade from Microsoft Dynamics AX 2012.

**Is the Tier 2 Azure SQL database sized enough for upgrades of large databases?**

If the database size grows, a Tier 2 sandbox that is deployed on an "elastic pool" should automatically be resized as required.

**Does the AX 2012 Database Upgrade Toolkit for Dynamics 365 support the Microsoft Government Community Cloud?**

No, the AX 2012 Database Upgrade Toolkit for Dynamics 365 doesn't currently support the Government Community Cloud (GCC).

**What type of validation is done as part of the AX 2012 Database Upgrade Toolkit for Dynamics 365?**

Few validations are done as part of the AX 2012 Database Upgrade Toolkit for Dynamics 365. For example, the toolkit validates that you've installed the required KBs (prerequisites) in AX 2012. If you haven't installed them, you can't start the replication process. There is also an option to run a record count check on the replicated data.

**What is the recommended approach if the source AX 2012 database is in a different region than the target database?**

For optimal replication performance, we recommend that the source AX 2012 database and the target database be in the same region. Customers can deploy the sandbox environment in the same region as the source and do the data upgrade. Then, after the upgrade is completed, the sandbox environment can be moved to the required region.

**Are the SQL BACPAC and DACPAC processes still supported for AX 2012 data upgrades in sandbox environments?**

No, the SQL BACPAC and DACPAC process are no longer supported for AX 2012 data upgrades in sandbox environments. Customers must use the AX 2012 Database Upgrade Toolkit for Dynamics 365 to do data upgrades in sandbox environments.

I've upgraded an AX 2012 database in a cloud hosted environment (dev) and uploaded the upgraded BACPAC file into Lifecycle Services. However, I receive an error message when I then try to import the BACPAC file into a sandbox environment. How do I fix the error?

When you try to import an upgraded BACPAC file from Microsoft Dynamics Lifecycle Services (LCS) into a sandbox environment, you might receive the following error message:
Importing AX 2012 bacpac file into Dynamics 365 environment isn't supported as it would result in a loss of the imported data and would put the environment in a failed state.

Validation is done to prevent a BACPAC file from being imported into a sandbox environment. For the AX 2012 database upload into a sandbox environment, you must use the AX 2012 Database Upgrade Toolkit for Dynamics 365, which utilizes SQL replication to transfer the data.

Can I filter on the table data that will be replicated (for example, to limit specific records only for replication to the target database)?

No, the AX 2012 Database Upgrade Toolkit for Dynamics 365 doesn't support filtering on the table data that will be replicated.
In Microsoft Dynamics AX 2012, you could use the same delimiter for your chart of accounts and dimension values. In current versions of Finance and Operations, you cannot have the same delimiter for the chart of accounts and dimension values. If there is a duplicate delimiter, you can change it after upgrade.

**Update delimiter**

If there is a conflict with the chart of accounts, the chart of accounts delimiter and the project/subproject ID format can be changed. No other dimension delimiters can be changed.

- You can change the chart of accounts delimiter after upgrade in **General ledger parameters > Chart of accounts and dimensions > Change delimiter**.
- If the only conflict is with the project/subproject ID format, you can change that value in **Project management and accounting parameters > General > Modify subproject format**.

**How to determine if your environment requires updated delimiters**

If delimiters in your upgraded environment are conflicting, you may experience instability when entering values in a segmented entry control or dimension entry control. This means that you will need to always use lookups or a flyout menu when entering account and dimension combinations.
This topic provides information about the Project resource scheduling data model.

Physical data model for Project resource scheduling

The following diagram represents the data design structure of the Project resource scheduling physical data model.

Tables

The following table provides a list of additional tables that support the Resource management data model.

<table>
<thead>
<tr>
<th>TABLE</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResResourceIdentifier</td>
<td>Stores all resources and a subset of records from the WrkCtrTable table that are identified as resources. When a resource is added, a record will be added to the WrkCtrTable table. A record will also be added to this table with a Foreign Key reference to the new record in the WrkCtrTable table.</td>
</tr>
<tr>
<td>ResourceSetup</td>
<td>Specifies a resource’s property. This table replaced the ProjWorkerSetup table in Dynamics AX 2012.</td>
</tr>
<tr>
<td>ResBooking</td>
<td>Stores all resource booking type reservations. This table replaced some of the information stored in the PSASchedEmplReservation table in Dynamics AX 2012.</td>
</tr>
</tbody>
</table>
TABLE | DESCRIPTION
--- | ---
ResAssignment | Stores all resource assignment type reservations. This table replaced some of the information stored in the PSASchedEmpRes table in Dynamics AX 2012.
ResourceCategorySetup | Stores the resource default project role association that is validated by a time range. This is a time effective table which has a Foreign Key to ResResourceIdentifier.RecId and a Foreign Key to PSASchedRole.RecId with ValidFrom and ValidTo fields. The PSASchedRole table is used to store the project role.
ResCalendarCapacity | This is a data denormalized table based on WorkCalendarTable, WorkCalendarDate, and WorkCalendarDateLine to calculate resource capacity. The calculation is based on the resource associated calendar date line definition, which is specified in the WorkCalendarDataLine table. The data in this table can be generated by running the Synchronize resource capacity roll-ups batch job.
ResRollUpCalendar | This is a data denormalized table based on ResCalendarCapacity. The data in this table is used by the ResRollUpWriter class to speed up the process of adding resource records to the ResRollup table. The data in this table can be generated by running the Synchronize resource capacity roll-ups batch job.
ResRollUp | This is a data denormalized table based on ResBooking, ResAssignment, and ResRollUpCalendar for performance improvement. This table contains all of the capacity and reservation data for time scales, including Day, Week, Month, Quarter, and Half year, for all resources. This data is accessed by the AvailabilityView control, which is included with any resource scheduling X++ form that includes this control, like the Resource availability form. The data in this table can be generated by running the Synchronize resource capacity roll-ups batch job. Data is updated for every resource reservation action such as adding a new resource, booking, assignment, and reservation cancellation.

Views
The following table provides a list of the most informative views that you can use to access the Resource management data model.

VIEW | DESCRIPTION
--- | ---
ResResourceWorkCenterView | This view is based on ResResourceIdentifier joining to WrkCtrTable, which captures only the fields that are required for resource management.
ResourceView | This view is based on ResResourceIdentifier, which is only based on ResResourceWorkCenterView. In a future release it can be extended to more than ResResourceWorkCenterView if a resource record will be saved on more than just ResResourceWorkCenterView.
<table>
<thead>
<tr>
<th>VIEW</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceWorkerView</td>
<td>This view replaces the HcmWorker table, which is based on ResResourceIdentifier. WrkCtrTable has a worker field which is a Foreign Key to HcmWorkerTable. This view includes all WrkCtrTable resource which worker field is not 0.</td>
</tr>
<tr>
<td>ResourceLegalEntityView</td>
<td>This view replaces the HcmEmployment table. This is the resource legal entity (LE) view, which is a union of ResourceWorkerLegalEntityView and ResourceOtherLegalEntityView. The purpose of this view is to look up the resource legal entity as well as the associated valid from and valid to date. For example, an HcmWorker resource can be hired by multiple LEs with different ValidFrom and ValidTo dates. If the worker is hired by multiple LEs, then this worker resource will have multiple records in this view. If the resource is not a HcmWorker, then this resource will have only one record and validFrom = minDate and ValidTo = maxDate.</td>
</tr>
<tr>
<td>ResourceCalendarView</td>
<td>This view replaces WorkCalendarTable. This view contains the calendar RecId of the resource. This is a union view of ResourceWorkerCalendarView, ResourceOtherCalendarView, and ResourceGroupResourceCalendarView. To look up the resource calendar, users should first look up the ResourceLegalEntityView. This is because a resource should have a different calendar depending on the resource's legal entity. First, locate the record from ResourceLegalEntityView and get the RefRecId and RefTableId fields. Then, look up ResourceCalendarView by setting ResourceLegalEntityRefRecId = ResourceLegalView.RefRecId and ResourceLegalEntityRefTableId = ResourceLegalView.RefTableId.</td>
</tr>
<tr>
<td>ResourceCategoryView</td>
<td>This view shows the resource category (the resource role for a worker resource), which is based on the PSASchedRole table.</td>
</tr>
<tr>
<td>ResSkillHcmView</td>
<td>This view is based on HcmSkill to capture all the skills that are defined in the HcmSkills table.</td>
</tr>
<tr>
<td>ResCertificateHcmView</td>
<td>This view is based on HcmCertificateType to capture all the certificates that are defined on the HcmCertificateType table.</td>
</tr>
<tr>
<td>ResEducationHcmView</td>
<td>This view is based on HcmEducationDiscipline to capture all the education disciplines that are defined in the HcmEducationDiscipline table.</td>
</tr>
<tr>
<td>ResProjectHcmView</td>
<td>This view is based on ProjTable to capture all projects that exist in the ProjTable.</td>
</tr>
<tr>
<td>ResRoleView</td>
<td>This view is based on ResourceCategoryView to capture all resource categories.</td>
</tr>
</tbody>
</table>
### VIEW DESCRIPTION

<table>
<thead>
<tr>
<th>VIEW</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResCharacteristicView</td>
<td>This view is the union view of ResSkillHcmView, ResCertificateHcmView, ResEducationHcmView, ResProjectHcmView, and ResRoleView. This view is used to gather all the characteristics that are defined as selectable criteria for the resource search feature.</td>
</tr>
<tr>
<td>ResResourceCharacteristicView</td>
<td>This view is the union view of ResResourceCharacteristicHcmView, ResResourceResourceCategoryView, ResResourceNameView, and ResResourceRoleCharacteristicView. This view is used to identify the characteristics that are associated with a resource for the resource search feature.</td>
</tr>
<tr>
<td>ResCalendarCapacityView</td>
<td>This view is based on ResCalendarCapacity, which contains calendars that are specified in WorkCalendarTable with capacity details.</td>
</tr>
<tr>
<td>ResCapacityView</td>
<td>This view shows the resource's capacity per hour.</td>
</tr>
<tr>
<td>ResResourceCapacityWorkDaysView</td>
<td>This view is based on ResCapacityView, which shows the resource capacity per day.</td>
</tr>
<tr>
<td>ResAssignmentView</td>
<td>This view is based on the table ResAssignment, which stores the activity resource assignments to either project or quotation work breakdown structure (WBS) task.</td>
</tr>
<tr>
<td>ResBookingView</td>
<td>This view is based on the table ResBooking, which stores the activity resource bookings to a project or quotation.</td>
</tr>
</tbody>
</table>

### Changes that will affect tables and fields

These sections contain information regarding code changes to tables and fields that are part of the feature implementation related to Project resource scheduling.

**Resource scheduling**

The table PSASchedEmpResReservation is no longer used to store a resource’s reservations. Instead, reservations are stored in the ResAssignment and ResBooking tables. Both tables use the **Activity resource** field Foreign Key for PSAProjSchedRole.RecId to store a resource’s reservation. The PSAProjSchedRole table is the project team table that has the **Resource** field Foreign Key to ResourceView.RecId and the **ResourceLegalEntity** field Foreign Key to CompanyInfo.RecId to identify which resources are the project’s or quotation’s team members. If the PSAProjSchedRole.Resource field = 0, then this activity resource is a planned resource. A planned resource is a shadow resource that is not backed by an actual resource. PSAProjSchedRole.ResourceCategory is a Foreign Key to PSAProjSchedRole that stores the role of this team member. The ResourceResourceCategorySetup table stores the default time effective resource/role association. However, the resource can be reserved to any role defined by PSAProjSchedRole.ResourceCategory, ignoring the default role definition on the ResourceResourceCategorySetup table. Regarding WBS versioning, the tables ProjPlanVersions and ProjPlanVersionDetails store the WBS tasks versions. Initially, all WBS task data will be stored on these tables while the user is editing the WBS tasks content. After the user clicks the Publish button, the task data will be pushed to the original hierarchy tables (smmActivities and PSAActivitySetup). The resource management feature requires data in the original hierarchy tables and requires a published WBS.

**Price by resource and resource category**
The pricing tables, ProjCostPriceExpense, ProjCostSalesPrice, and ProjRevenueSalesPrice have a Foreign Key from ResourceView.ReclId. The tables ProjHourCostPrice, ProjHourSalesPrice, and ProjTransferPrice have a Foreign Key from ResourceView.ReclId. The field ResourceCategory is part of the Foreign Key for ResourceCategoryView.ReclId. This is done so that pricing is based on a resource instead of a worker and enables pricing setup by resource category.

Common methods to get resource field and lookup resources
There are several resource methods in the ResourceFacade class. The following table includes some of the most common methods.

<table>
<thead>
<tr>
<th>CLASS METHOD</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceFacade.findByWorker()</td>
<td>Look up the resource record ID by HcmWorker record ID.</td>
</tr>
<tr>
<td>ResourceFacade.findOrCreateByWorker()</td>
<td>Look up the resource record ID by HcmWorker record ID. If the resource record ID is not found, then a resource record ID will be added to the ResResourceIdentifier table and the resource record ID will be returned.</td>
</tr>
<tr>
<td>ResourceFacade.findByResourceID()</td>
<td>Look up the resource record ID by resource ID.</td>
</tr>
<tr>
<td>ResourceFacade.get...</td>
<td>There are many get methods supported for the resource in the ResourceFacade class. Resource related values like Resource ID, Resource calendar, Resource legal entity, and Resource period can be queried from the ResourceView, ResourceLegalEntityView, ResourceCalendarView, and ResourceSetup tables.</td>
</tr>
</tbody>
</table>

Facade classes
The following table lists the facade classes that you can use as a starting point to interact with the Resource management data model.

<table>
<thead>
<tr>
<th>CLASS</th>
<th>DESCRIPTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActivityFacade</td>
<td>Contains the methods to retrieve an activity's properties, including ID, Quotation ID, Project ID, Booked/assigned capacity, Remaining capacity, Calendar, Activity number, and Root project activity.</td>
</tr>
<tr>
<td>ActivityResourceFacade</td>
<td>Contains the methods to retrieve an activity's resource properties including Calendar, Name, Resource category, Resource legal entity, Is generic resource, and Is team member.</td>
</tr>
<tr>
<td>PeriodFacade</td>
<td>Contains the methods to retrieve period properties including Start and End date, Period ID, and Period name.</td>
</tr>
<tr>
<td>ResourceCalendarFacade</td>
<td>Contains the methods to retrieve the resource's calendar properties including Calendar data area ID, Calendar ID, Calendar RecID, Capacity, and Dates.</td>
</tr>
<tr>
<td>ResourceCategoryFacade</td>
<td>Contains the methods to retrieve the resource's default resource Category, ID, Name, and Type.</td>
</tr>
<tr>
<td>CLASS</td>
<td>DESCRIPTION</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ResourcePeriodFacade</td>
<td>Contains the methods to retrieve the resource's period date range and update the period method.</td>
</tr>
<tr>
<td>ResourceWorkerFacade</td>
<td>Contains the methods to retrieve the Employment type.</td>
</tr>
</tbody>
</table>
This topic reviews the workflow system in Finance and Operations. It describes the changes that have been implemented since Microsoft Dynamics AX 2012 and also includes links to more information about the workflow system.

The workflow system in Finance and Operations will be familiar to you if you’ve used Dynamics AX 2012. For more information about the workflow subsystem in Dynamics AX 2012, see the following topics.

**Primary changes to the workflow system**

Here are the primary changes that have been implemented in Finance and Operations:

- Integration with the new Application State Machine feature enables workflow events to be bound to state transitions on the underlying entity’s state machine. This binding enables business logic to be centralized within the state machine and also enables the workflow system to be a declarative consumer of that state machine. The workflow metadata can reference a state transition that is performed when a specific workflow event occurs. Therefore, you can do state transitions within a workflow without writing any additional code.

- The workflow editor is now a program that you click one time to download. The editor communicates with Finance and Operations by using services, which means that you can carry forward the rich, graphical workflow design experience from Dynamics AX 2012.

- Workflow development wizards have been ported into Microsoft Visual Studio.

*Technical Concepts Guide for Developers*
Transition from Analysis Services cubes to aggregate models

This topic explains how in-memory, real-time aggregate models are used for analytics, and why we transitioned from using Server Analysis Services (SSAS) cubes.

The world is moving to real-time, proactive analytics. Reporting and trending on historical data is being replaced by up-to-the-second visualizations and proactive guidance. In-memory, real-time aggregate models now replace the perspectives that were previously used for analytics.

A historical look at perspectives and cubes

We envision embedded insights playing a key role in the Finance and Operations user experience. This vision has driven us to invest in building analytic capabilities within the product. In Dynamics AX 4.0, we introduced the concept of perspectives. The objective was to present a simpler view of the ERP schema, specifically modeled for reporting. This simpler view was referred to as perspectives. In Dynamics AX 4.0, the system generated reporting models (SMDL models) that enabled you to create ad-hoc reports with SQL Server Report Builder. In Dynamics AX 2009, we added the capability to generate SQL Server Analysis Services (SSAS) projects using metadata definitions in perspectives. These projects become cubes when deployed to an SSAS server. In Dynamics AX 2012, we improved modeling in perspectives and improved tooling support for managing the lifecycle of SSAS projects. You could use Excel, as well as Power View, to explore data and create reports with cubes in Dynamics AX 2012. The SMDL technology was also deprecated. In Dynamics AX 2012, we stopped generating SMDL models.

How perspectives are used now

As a developer, your “contract” with the system was a perspective. The system generated “stuff” to help you achieve your end goal. In Dynamics AX 2012, the “stuff” that was generated was SSAS projects. So the contract between you (the developer) and the system (the BI framework), was as follows:

- You modeled perspectives.
- The system generated the “stuff” needed to enable you to build visuals and reports.

Perspectives are now modeled using add-ins for Visual Studio. (Visual Studio is now the development environment.) Perspectives are comprised of aggregate measurements and aggregate dimensions. As a developer, you have the ability to model simpler schemas for answering business questions using aggregate measurements and aggregate dimensions. Aggregate measurements can be used to define data entities (called aggregate data entities) which can be directly bound to Finance and Operations forms as a data source. Aggregate data entities can also be used to

- Expose data to PowerBI.
- Access data programmatically using the AXQuery object.
Model Aggregate Data entity

New constructs to model expressions and aggregates
In this tutorial, you'll migrate an upgraded Microsoft Dynamics AX 2012 R3 cube schema to the entity store in a Finance and Operations application. You'll use the sales cube that was included in Dynamics AX 2012 R3 as an example.

The entity store will support near real-time Microsoft Power BI integration scenarios, as shown in the following diagram. For an overview of Power BI integration with entity store, see Power BI integration with entity store.

New Power BI features included in the May 2016 and November 2016 updates

This tutorial requires the Dynamics 365 for Operations May 2016 update or later. You will use the following new capabilities in this tutorial:

- Stage an aggregate measurement in the entity store and refresh the data from Dynamics AX. You might prefer this option over in-memory real time aggregate measurements when:
  - You upgrade a Dynamics AX 2012 cube.
  - Your aggregate measurements are very large.
  - Data freshness (latency) from a few minutes up to a few hours is acceptable for reporting.
- Use the batch framework to schedule a recurring refresh. For this release, only a full refresh is enabled.
- Create reports using Power BI desktop in a developer/test environment.
- Leverage the direct query option when creating Power BI content. For example, you can create larger models without relying on OData as the data refresh mechanism.
- Migrate reports from your development environment to a production environment using Lifecycle Services (LCS).
- As a partner or an ISV you can distribute Power BI content as part of an LCS solution to your customers.
- If you're using the November update (platform release 1611) or later, some steps in this document...
Change upgraded aggregate measurement properties

As part of the code upgrade process, analysis services projects from the Application Object Tree (AOT) in Dynamics AX 2012 can be migrated to the new aggregate measurements metadata format.

1. Launch Visual Studio and create a new project in Application Suite.

   **NOTE**
   You can create a model and include the customized aggregate measurement within that model. For more information, see [Customize through extension and overlayering](#).

2. Open Application Explorer. Go to **Analytics > Perspectives > Aggregate measurements**. You will notice a set of aggregate measurements that were upgraded from Dynamics AX 2012 R3, as well as the measurements that ship in the current version.

3. Select **SalesCube**. Right-click and select **Duplicate in project**.

4. An aggregate measurement with the name **SalesCubeCopy** will be added to the project.

5. Rename this measurement. Select **SalesCubeCopy** in Solution Explorer. Right-click and select **Rename**. Enter **SalesCubeV2** as the new name.

6. Double-click **SalesCubeV2** to launch the Aggregate measurement designer. Notice the structure of the aggregate measurement that was migrated from Dynamics AX 2012.

7. The Sales cube in Dynamics AX 2012 encompassed a broad subject area related to Sales. In this case, let's create a smaller, more focused Power BI model using the metadata that was upgraded. Expand the **Sales Order Lines** measure group and review the list of measures and dimension references.

   **NOTE**
   Leveraging the modeling capabilities you can quickly make a few enhancements to this model. Suggestions for improvements:
   - Replace views/tables that have been used to model the measure group (and/or dimensions) with an entity. You can model an entity using the underlying view and replace the view with the corresponding entity. This will enable you to leverage upcoming features such as incremental refresh and security.
   - Remove unwanted dimension references by adding the corresponding field to the attributes node. For example, the Sizes dimension reference can be removed because the **Size** field in the measure group is sufficiently descriptive. This will improve the runtime performance of queries as well as refresh times.

8. Select the **SalesCubeV2** root node in the Aggregate measurement designer. Right-click and select **Properties**.

9. During upgrade, aggregate measurements are set to the legacy property flag, **SSASCube**. You need to change this property to one of two supported usage types. Previously, **InMemoryRealTime** was supported as usage for aggregate measurements. **StagedEntityStore** is supported as a new usage type.

   **NOTE**
   Modify the usage property to **InMemoryRealTime** if you plan to use the Aggregate measurement for embedded BI scenarios as well as Power BI integration. If you are using the Aggregate measurement only for Power BI or Cortana Intelligence Suite integration, select **StagedEntityStore**.
10. Save the project. Right-click the project in Solution Explorer and select **Rebuild**.

11. After the rebuild operation is finished, save the project, and then close Visual Studio. This completes the development work. You will author reports as a report developer or a power user.

**Refresh the entity store**

As an administrator you can configure the refresh of the aggregate measurement using the client.

1. Launch the Dynamics AX client and navigate to **System Administration > Setup > Entity Store**. The **Entity Store** form shows a list of aggregate measurements that are available for deployment to the entity store.

2. Notice that **Sales Cube** (which was upgraded from Dynamics AX 2012) is not available for deployment to the entity store. **SalesCubeV2**, which you created in the previous step, can be deployed to the entity store.

3. Select **SalesCubeV2** from the list, and click the **Refresh** button. The **Refresh** dialog box will display. Expand the **Run in the background** tab.

4. Provide a descriptive name in the **Task description** field. Optionally, you can select the **Recurrence** tab and create a recurring schedule instead of a one-time refresh. Click **OK**.

5. The system will create a batch job for refresh of the aggregate measurement in the entity store.

**Authoring a report on Sales by State with Power BI desktop**

This step requires that you install Power BI desktop tool that can be downloaded from [Microsoft Power BI Desktop](#).

1. Launch Power BI desktop. You may need to apply updates. A welcome page will display. Click **Get data**.

2. Alternatively, when Power BI desktop launches, on the **Home** tab select **Get Data > SQL Server**.

3. In the **SQL Server Database** dialog box, enter the server name and the name of the entity store database. If you deployed a developer environment, you can enter ‘.’ as the server name and **AxDW** as the database name. If you are working in a test environment, you need to get these parameters from your system administrator.

4. Select the **DirectQuery** option. In this exercise, you will create Power BI reports that are executed directly on the entity store. If you had used the **Import** option, Power BI would cache data from the entity store and you would need to periodically refresh the Power BI model. **Import mode is currently not supported with reports written using entity store**. Click **OK**.

5. Next you will see the **Navigator** dialog box. Navigator enables you to select tables and views from the entity store that you want to report on. Enter **Sales** in the search box. The system will filter entities that are related to the **SalesCubeV2** aggregate measurement that was previously created.

   **NOTE**

   The entity store stages the aggregate measurements that have been created. While entities within each aggregate measurement are prefixed and stored as individual tables, Power BI desktop enables you to combine data from multiple aggregate measurements.

6. You will create a report that shows sales by state. Select **SalesCubeV2_Customer** and **SalesCubeV2_CustomerInvoices** from Navigator and click **Load**.

7. You will notice Power BI designer with **Fields** present in the entities that you have chosen (on the far right), as well as available visualization.

**Create a surrogate key that links customers and invoices (applies to Platform versions before November 2016)**
Surrogate keys are generated in aggregate measurements staged into entity store. Power BI desktop does not enable you to relate table joins using multiple fields (also known as, composite keys). The SalesCubeV2_Customer entity does not have a surrogate key (such as AX RecID) defined in it. Next, you will create a surrogate key that enables relating a customer entity to invoices.

1. Select the ellipsis (…) icon next to the SalesCubeV2_CustomerInvoices entity. Right-click and select New Column.

2. Enter the following expression in the Formula editor window.

   \[ \text{FKCustomer} = \text{CONCATENATE(CONCATENATE(SalesCubeV2_CustomerInvoices[DATAAREAID], "-"), SalesCubeV2_CustomerInvoices[ORDERACCOUNT])} \]

3. When completed, your formula should look similar to the following.

4. Notice that a new field, FKCustomer, is shown in the list of fields for the SalesCubeV2_CustomerInvoices table. Because this field is used to relate two tables, you can hide it from end users by right-clicking the field and selecting the Hide option.

5. Next, create a similar field in the SalesCubeV2_Customer table. Select the ellipsis (…) icon next to SalesCubeV2_Customer entity. Right-click and select New Column.

6. Enter the following expression in the Formula editor window.

   \[ \text{FKCustomer} = \text{CONCATENATE(CONCATENATE(SalesCubeV2_Customer[DATAAREAID], "-"), SalesCubeV2_Customer[CUSTOMER])} \]

7. Notice that the field FKCustomer is shown in the list of fields for the SalesCubeV2_Customer table. Because this field is used for relating two tables, you can hide it from end users by right-clicking the field and selecting the Hide option.

Relate invoices and customers
NOTE
You can relate the surrogate keys already created within entity store. If not, you must relate the surrogate keys that you created manually. Next you will create a relationship between SalesCubeV2_CustomerInvoices and SalesCubeV2_Customers entities.

1. Click the Manage Relationships button on the Power BI ribbon. You will see the Manage Relationships dialog box. Click the New button.
2. In the Create Relationship dialog box, select SalesCubeV2CustomerInvoices as the first table in the drop-down list. Scroll to the right and select the FKCustomer field as the column to relate to.
3. In the second drop-down list select SalesCubeV2Customer as the table. Scroll to the right and select FKCustomer as the column to relate to.
4. Select the Make this relationship active option if it is not already selected. Click OK to continue.
5. You will notice the newly created relationship in the Manage Relationships dialog box. Click the Close button.

Create a Sales by state report
1. To create a report that shows sales by customer group, drag the CustomerInvoiceAmountAccountingCurrency field from the SalesCubeV2_CustomerInvoices table and drop it on the Power BI desktop canvas. Next, drag the CustomerGroupName field in the SalesCubeV2_Customer table to the same grid.
2. Change the chart type to a doughnut chart. You should see a report similar to the following.

3. You can create additional visuals using the Power BI desktop. When you save, you will notice that the file has a PBIX extension.
4. Save the report to your desktop.
5. At this point the report is fully functional (with data from your environment) and you can continue to use the Power BI desktop or upload this report to PowerBI.com and continue with data exploration.
6. Next, you will migrate this report to a production environment using LCS so that you can see this report with production data and share it with other users.

**Publish the report and the model**

Publishing a report and model requires uploading the report to Lifecycle Services, migrating the aggregate measurement to your production environment, configuring the client to point to the correct LCS library, and publishing your reports in your production environment.

**Upload the report to Lifecycle Services**

Microsoft Dynamics Lifecycle Services (LCS) is the tool used to migrate development artifacts from developer to production environments. In the May 2016 update, LCS supports migrating PBIX files (authored using the entity store) between environments.

1. Open LCS from the developer environment. If you haven’t created a project in the LCS environment, create a project.
2. Scroll to the right and you will notice the **Asset Library** icon. Click the icon and launch **Asset Library**.

Notice that the asset library enables adding **PowerBI report models** (PBIX files) as implementation artifacts to a project.

1. Select the plus (+) icon to add a new asset.
2. Provide a name and a description. Click **Upload** and then locate the file that you saved in an earlier step.
